SERIES V: DATA COMMUNICATION OVER THE
TELEPHONE NETWORK

Interworking with other networks

**Support by an ISDN of data terminal equipments
with V-series type interfaces**

ITU-T Recommendation V.110

(Formerly CCITT Recommendation)

ITU-T V-SERIES RECOMMENDATIONS
DATA COMMUNICATION OVER THE TELEPHONE NETWORK

General	V.1–V.9
Interfaces and voiceband modems	V.10–V.34
Wideband modems	V.35–V.39
Error control	V.40–V.49
Transmission quality and maintenance	V.50–V.59
Simultaneous transmission of data and other signals	V.60–V.99
Interworking with other networks	V.100–V.199
Interface layer specifications for data communication	V.200–V.249
Control procedures	V.250–V.299
Modems on digital circuits	V.300–V.399

For further details, please refer to ITU-T List of Recommendations.

**SUPPORT BY AN ISDN OF DATA TERMINAL EQUIPMENTS
WITH V-SERIES TYPE INTERFACES**

Summary

This Recommendation defines terminal adaptor (TA) functions for the connection of terminals having interfaces conforming to current V-series Recommendations to the ISDN for both circuit switched and leased circuit services. This includes the following functions:

- conversion of electrical and mechanical interface characteristics;
- bit rate adaption;
- end-to-end synchronization of entry to and exit from the data transfer phase;
- call establishment and disestablishment based on either manual or automatic calling and/or automatic answering;
- local and end-to-end flow control to support DTEs of differing rates.

Source

ITU-T Recommendation V.110 was revised by ITU-T Study Group 16 (1997-2000) and was approved under the WTSC Resolution No. 1 procedure on 17 February 2000.

FOREWORD

ITU (International Telecommunication Union) is the United Nations Specialized Agency in the field of telecommunications. The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of the ITU. The ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Conference (WTSC), which meets every four years, establishes the topics for study by the ITU-T Study Groups which, in their turn, produce Recommendations on these topics.

The approval of Recommendations by the Members of the ITU-T is covered by the procedure laid down in WTSC Resolution No. 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

INTELLECTUAL PROPERTY RIGHTS

The ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. The ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, the ITU had not received notice of intellectual property, protected by patents, which may be required to implement this Recommendation. However, implementors are cautioned that this may not represent the latest information and are therefore strongly urged to consult the TSB patent database.

Recommendation V.110

SUPPORT BY AN ISDN OF DATA TERMINAL EQUIPMENTS WITH V-SERIES TYPE INTERFACES

*(Malaga-Torremolinos, 1984; amended at Melbourne, 1988;
revised at Geneva in 1992, 1996 and 2000)*

1 Scope

The ITU-T,

considering

- a) that the ISDN will offer the universal interfaces to connect subscriber terminals according to the reference configuration described in Recommendation I.411;
- b) that during the evolution of ISDN, however, there will exist for a considerable period data terminal equipments (DTEs) with V-series type interfaces which have to be connected to the ISDN;
- c) that bearer services supported by an ISDN are described in Recommendation I.211;
- d) that the D-channel signalling protocol is described in Recommendations I.430, Q.921 and Q.931,

unanimously declares the view

- 1 that the scope of this Recommendation shall cover the connection of terminals with interfaces for modems conforming to current V-series Recommendations on the ISDN operating in accordance with circuit switched or leased circuit services;
- 2 that the following circuit switched service capabilities shall be supported:
 - data transmission; (and optionally)
 - automatic calling and/or automatic answering;
- 3 that the reference configurations of clause 4 shall apply;
- 4 that the support of interworking of terminal equipments (TEs) on an ISDN with DTEs on other types of networks, e.g. public switched telephone network (PSTN), is described in the I.500-series Recommendations;
- 5 that the terminal adaptor (TA) functions necessary to support the connection of DTEs with V-series type interfaces on an ISDN shall include the following:
 - conversion of electrical and mechanical interface characteristics;
 - bit rate adaption;
 - end-to-end synchronization of entry to and exit from the data transfer phase;
 - call establishment and disestablishment based on either manual or automatic calling and/or automatic answering;
- 6 that optionally, the following may be included:
 - local and end-to-end flow control to support DTEs of differing bit rates.

3 Abbreviations

This Recommendation uses the following abbreviations:

CFI	Call Failure Indication
CRI	Call Request with Identification
CRN	Call Request with Number
DC	Device Control
DC1	Device Control one
DC3	Device Control three
DCE	Data Circuit-Terminating Equipment
DTE	Data Terminal Equipment
DTR	Data Terminal Ready
IA5	International Alphabet No. 5
ISDN	Integrated Services Digital Network
ISO	International Organization for Standardization
IWF	Interworking Function
NT	Network Termination
PARAM-X	Parameter X (X = 0, 1, 2, 3, 4)
ppm	parts per million
PSTN	Public Switched Telephone Network
RA	Rate Adaption
RD	Received Data
TA	Terminal Adaptor
TA-A	Terminal Adaptor – Type A
TA-B	Terminal Adaptor – Type B

TD	Transmitted Data
TE	Terminal Equipment
TE1	Terminal Equipment type 1
TE2	Terminal Equipment type 2
TH	Threshold
Tn	Timer n (n = 1, 2, 3)

4 Reference configurations

4.1 Terminal adaptor reference model

The terminal adaptor functions have been defined in the context of a simple reference model. Annex A describes the reference model in further detail, and defines a basic terminal adaptor TA-A, and an auto-calling/auto-answering terminal adaptor TA-B.

4.2 Connection types

The terminal adaptor functions described in this Recommendation take into account interworking between TAs of different types, e.g. V-series TE2 with X.21 TE2, and end-to-end connections of different types. These are described in further detail in Annex A.

5 Line signals at S and T reference points

The TA signals at ISDN reference points S or T shall be in conformance with the characteristics of an ISDN's "Basic user/network interface" as described in Recommendations I.430 (layer 1 specification), Q.921 (layer 2 specification) and Q.931 (layer 3 specification).

5.1 Bit rate adaption of synchronous data signalling rates up to 38.4 kbit/s

5.1.1 General approach

The bit rate adaption functions within the TA are shown in Figure 1. The function RA1 converts the user data signalling rate to an appropriate intermediate rate expressed by $2^k \times 8$ kbit/s (where $k = 0, 1, 2$ or 3). RA2 performs the second conversion from the intermediate rates to 64 kbit/s. The data signalling rates of 48 and 56 kbit/s are converted directly into the 64-kbit/s B-channel rate. The intermediate rate of 64 kbit/s is directly mapped into the 64-kbit/s B-channel rate.

Figure 1/V.110 – Two-step bit rate adaption

5.1.2 Adaption of V-series data signalling rates to the intermediate rates

The intermediate rate used with each of the V-series data signalling rates are shown in Table 1.

Table 1/V.110 – First step rate adaption

Data signalling rate (bit/s)	Intermediate rate			
	8 kbit/s	16 kbit/s	32 kbit/s	64 kbit/s
600	X			
1 200	X			
2 400	X			
4 800	X			
7 200		X		
9 600		X		
12 000			X	
14 400			X	
19 200			X	
24 000				X
28 800				X
38 400				X

5.1.2.1 Frame structure

The frame structure is shown in Table 2 and is described in the following paragraphs.

Table 2/V.110 – Frame structure

Octet number	Bit number							
	1	2	3	4	5	6	7	8
0	0	0	0	0	0	0	0	0
1	1	D1	D2	D3	D4	D5	D6	S1
2	1	D7	D8	D9	D10	D11	D12	X
3	1	D13	D14	D15	D16	D17	D18	S3
4	1	D19	D20	D21	D22	D23	D24	S4
5	1	E1	E2	E3	E4	E5	E6	E7
6	1	D25	D26	D27	D28	D29	D30	S6
7	1	D31	D32	D33	D34	D35	D36	X
8	1	D37	D38	D39	D40	D41	D42	S8
9	1	D43	D44	D45	D46	D47	D48	S9

As shown in Table 2, the conversion of the V-series rates to the intermediate rates uses an 80-bit frame. The octet zero contains all binary 0, whilst octet 5 consists of a binary 1 followed by seven E bits (see 5.1.2.4). Octets 1-4 and 6-9 contain a binary 1 in bit number 1, a status bit (S- or X-bit) in bit number 8 and six data bits (D-bits) in bit positions 2-7. The order of bit transmission is from left to right and top to bottom.

5.1.2.2 Frame synchronization

The 17-bit frame alignment pattern consists of all 8 bits (set to binary 0) of octet zero and bit one (set to binary 1) of the following nine octets (see also 5.1.3).

5.1.2.3 Status bits (S1, S3, S4, S6, S8, S9 and X)

The bits S and X may be used to convey channel control information associated with the data bits in the data transfer state, as shown in Table 3. The S-bits are put into two groups SA (= S1, S3, S6, S8) and SB (= S4, S9), permitting the carriage of the condition of two interchange circuits. The X-bit is used to control the condition of circuit 106, and, in addition, signals the state of frame synchronization between TAs (see clause 7). The X-bit can also be used optionally to carry flow control information between TAs supporting asynchronous terminal equipment. This usage is specified in 5.4.2.

Table 3/V.110 – General mapping scheme at the TA during the data transfer state

V.24 interchange circuit at DTE/TA interface	Status bit mapping – Direction: TA to ISDN	Status bit mapping – Direction: ISDN to TA
105 (Note 3)	Mapped to SB	
106 (Note 1)		Mapped from X
107		Mapped from SA
108	Mapped to SA	
109		Mapped from SB
133 (Note 3)	Mapped to X (Note 2)	
<p>NOTE 1 – The condition of circuit 106 may also be affected by the state of any transmit buffer in the TA if end-to-end flow control is supported.</p> <p>NOTE 2 – The condition of status bit X towards the ISDN may also be affected by the state of any receive buffer in the TA if end-to-end flow control is supported.</p> <p>NOTE 3 – Circuits 105 and 133 are assigned to the same connector pin on the standardized 25- and 26-pole connectors (ISO/IEC 2110 and ISO/IEC 11569). As circuit 133 is used only in duplex operation and circuit 105 is used only in half-duplex operation, there should be no conflict. The status bit corresponding to the unassigned circuit shall be set to the ON condition during the data transfer state.</p>		

The use of S- and X-bits for synchronization of entry to and exit from the data transfer state is specified in clause 7.

Table 3 shows the general mapping scheme in the TA between the status bits and the V.24 interchange circuits at the DTE-TA interface during the data transfer state. Which circuits are actually mapped depends on the interoperational case (see A.4) and whether the DTE's mode of operation is duplex (see 7.1) or half duplex (see 7.2).

The mapping between the status bits and the modem (DCE) control circuits in an interworking function (IWF) is the same as in Table 3 except the directions of the mappings are reversed. For example, circuit 109 is an output from the IWF modem (DCE) and is mapped to status bit SB towards the ISDN.

For the S- and X-bits, a ZERO corresponds with the ON condition of the respective interchange circuit, a ONE with the OFF condition.

Control information, conveyed by the S-bits, and user data, conveyed by the D-bits, should not have different transmission delays. The S-bits should therefore transmit control information sampled simultaneously with the D-bits in the positions specified in Table 4 and as presented in Figure 2.

The X-bit should be presented upon arrival to control circuit 106. Circuit 106 shall respond as defined in 6.3 and, if the X-bit carries flow control information, in 7.2.

Table 4/V.110 – Coordination between S-bits and D-bits

S-bit	D-bit	
	Octet No.	Bit No.
S1	2	3 (D8)
S3	3	5 (D16)
S4	4	7 (D24)
S6	7	3 (D32)
S8	8	5 (D40)
S9	9	7 (D48)

5.1.2.4 E-bit usage

The E-bits are used to carry the following information:

- Rate repetition information:* Bits E1, E2 and E3, in conjunction with the intermediate rate (see Table 2), provide the user data signalling rate (synchronous) identification. The coding of these bits shall be as shown in Table 5.
- Network-independent clock information:* Bits E4, E5 and E6 are used as specified in clause 8 to carry network-independent clock phase information.
- Multiframe information:* Bit E7 is used as indicated in Table 5.

Table 5/V.110 – E-bit usage (Note 1)

Intermediate rates kbit/s				E1	E2	E3	E4	E5	E6	E7
8	16	32	64	(Note 4)		(Note 3)				
bit/s	bit/s	bit/s	bit/s							
600				1	0	0	C	C	C	1 or 0 (Note 2)
1200				0	1	0	C	C	C	1
2400				1	1	0	C	C	C	1
		12 000	24 000	0	0	1	C	C	C	1
	7200	14 400	28 800	1	0	1	C	C	C	1
4800	9600	19 200	38 400	0	1	1	C	C	C	1

NOTE 1 – The data signalling rates of 600, 2400, 4800 and 9600 bit/s are also X.1 user classes of service (see also Recommendation X.30).

NOTE 2 – In order to maintain compatibility with Recommendation X.30, the 600 bit/s user rate E7 is coded to enable the 4 × 80 bit multiframe synchronization. To this end, E7 in the fourth 80-bit frame is set to binary 0 (see 5.1.2.7 and Table 6a).

NOTE 3 – C indicates the use of E4, E5 and E6 for the transport of network-independent clocking information (see clause 8). These bits shall be set to ONE when unused.

NOTE 4 – Synchronous rate information is carried by bits E1, E2 and E3 as indicated. Asynchronous rate information must be provided with out-of-band signalling (layer 3 messages in the D-channel) or with in-band parameter exchange as described in Appendix I.

5.1.2.5 Rate negotiation

Negotiation of the synchronous rate may be appropriate in interworking situations involving interconnections with modems on the PSTN where the remote modem/DTE has the capability of operating at different rates depending upon the conditions. It may also be appropriate in interconnections for asynchronous transmission specified in 5.3 and accommodate split rate operation. The need for rate negotiation and the method is for further study.

5.1.2.6 Data bits

Data are conveyed in D-bits, i.e. up to 48 bits per 80-bit frame. In this Recommendation the octet boundaries of the user's data stream are not defined.

5.1.2.7 Bit assignment

The adaption of 600, 1200 and 2400 bit/s rates to the 8 kbit/s intermediate rate are shown in Tables 6a, 6b and 6c, respectively.

The adaption of 7200, 14 400 and 28 800 bit/s rates to the 16, 32 and 64 kbit/s intermediate rate, respectively, use the data bit assignments shown in Table 6d.

The adaption of 4800, 9600, 19 200 and 38 400 bit/s rates to the 8, 16, 32 and 64 kbit/s intermediate rate, respectively, use the data bit assignments shown in Table 6e.

The adaption of 12 000 and 24 000 bit/s user rate to 32 and 64 kbit/s intermediate rate, respectively, use the data bit assignments shown in Table 6f.

Table 6a/V.110 – Adaption of 600 bit/s user rate to 8 kbit/s intermediate rates

5.1.3 Frame synchronization and additional signalling capacity

5.1.3.1 Search for frame synchronization

The following 17-bit alignment pattern is used to achieve frame synchronization:

```

00000000  1YYYYYYY      1YYYYYYY      1YYYYYYY      1YYYYYYY
1YYYYYYY  1YYYYYYY      1YYYYYYY      1YYYYYYY      1YYYYYYY

```

The bits marked 'Y' are not part of the frame alignment pattern. They carry the user data (D bits) and S and X status bits as shown in Table 2. To ensure a reliable synchronization, it is recommended that at least two 17-bit alignment patterns in consecutive frames be detected.

Once frame synchronization is achieved, it is recommended that a persistence check be made of the status bits $S = X = \text{OFF}$ condition of 7.1.2 prior to proceeding to transparent data transfer with the status bits $S = X = \text{ON}$ condition, as shown in Figure 3 and described in clause 7.

5.1.3.2 Frame synchronization monitoring and recovery

Monitoring of the frame synchronization shall be a continuous process using the same procedures as for initial detection.

Loss of frame synchronization shall not be assumed unless at least three consecutive frames, each with at least one framing bit error, are detected.

Following loss of frame synchronization, the TA shall enter a recovery state as discussed in 7.1.5. If recovery is not successful, further maintenance procedures may be used.

5.1.4 Adaption of intermediate rates to 64 kbit/s

Since rate adaption of a single intermediate rate (e.g. 8, 16, or 32 kbit/s) to the 64 kbit/s B-channel rate and the possible multiplexing of several intermediate rate streams¹ to the 64 kbit/s B-channel rate must be compatible to enable interworking, a common approach is needed for the second step rate adaption and, possibly, for intermediate rate multiplexing. This second step rate adaption method is described in Recommendation I.460.

5.2 Rate adaption of 48 and 56 kbit/s synchronous user rates to 64 kbit/s

The 48 and 56 kbit/s user data signalling rates are adapted to the 64 kbit/s B-channel rate in one step as indicated in Tables 7a, 7b or 7c respectively.

Table 7a/V.110 – Adaption of 48 kbit/s user rate to 64 kbit/s

Octet number	Bit number							
	1	2	3	4	5	6	7	8
1	1	D1	D2	D3	D4	D5	D6	S1
2	0	D7	D8	D9	D10	D11	D12	X
3	1	D13	D14	D15	D16	D17	D18	S3
4	1	D19	D20	D21	D22	D23	D24	S4
NOTE 1 – 48 kbit/s is also a X.1 user class of service (see also 2.2.1/X.30).								
NOTE 2 – Refer to 5.1.2.3 for the use of status bits and bit X; however for international operation over restricted 64-kbit/s bearer capabilities, bit X must be set to binary 1.								

¹ Multiplexing of several intermediate rate streams is for further study.

Table 7b/V.110 – Adaption of 56 kbit/s user rate to 64 kbit/s

8	D50	D51	D52	D53	D54	D55	D56	1
NOTE 1 – Refer to 5.1.2.3 for the use of status bits and bit X.								
NOTE 2 – This table is a permitted option to provide for signalling to enter and to leave the data phase. However, the recommended approach shall be as in Table 7b and the responsibility shall be on the user of this table to ensure that interworking can be achieved.								

5.2.1 Frame synchronization

At the user data signalling rate of 48 kbit/s, the frame alignment pattern consists of 1011 in bit 1 of consecutive octets of one frame. To ensure reliable synchronization, it is suggested that at least five 4-bit alignment patterns in consecutive frames be detected.

At the user data signalling rate of 56 kbit/s with the alternative frame structure according to Table 7c, the frame alignment pattern consists of 0YYY1111 in bit 8 of consecutive octets of one frame. Bits marked with Y may be either "0" or "1". To ensure a reliable synchronization, it is suggested that at least four 5-bit (01111) alignment patterns in the 8-bit sequence of 0YYY1111 in consecutive octets be detected.

Frame synchronization monitoring and recovery is described in 5.1.3.2.

5.3 Adaption for asynchronous rates of up to 38 400 bit/s

5.3.1 General approach

The bit rate adaption functions within the TA are shown in Figure 4. A three-step method is employed with the functional blocks RA0, RA1, and RA2. The RA0 function is an asynchronous-to-synchronous conversion step, for support of the rates specified in Table 8, using the same technique as defined in Recommendation V.14. It produces a synchronous bit stream defined by $2^n \times 600$ bit/s (where $n = 0$ to 6). The functions RA1 and RA2 are the same as specified in 5.1. Function RA1 adapts the user rate to the next higher rate expressed by $2^k \times 8$ kbit/s (where $k = 0, 1, 2$ or 3). RA2 performs the second conversion to 64 kbit/s.

Figure 4/V.110 – Three-step rate adaption bit

5.3.2 Supported asynchronous user rates

The asynchronous user rates to be supported, mandatory and optional, are specified in Table 8.

Table 8/V.110 – Asynchronous user rates

Data rate (bit/s)	Rate tolerance (%)	Number of data units	Number of stop elements	RA0/RA1 rate (bit/s)	RA1 rate (kbit/s)
50	±2.5	5	1.5	600	8
75	±2.5	5, 7 or 8	1, 1.5 or 2	600	8
110	±2.5	7 or 8	1 or 2	600	8
150	±2.5	7 or 8	1 or 2	600	8
200	±2.5	7 or 8	1 or 2	600	8
300*	±2.5	7 or 8	1 or 2	600	8
600*	+1 – 2.5	7 or 8	1 or 2	600	8
1 200*	+1 – 2.5	7 or 8	1 or 2	1 200	8
2 400*	+1 – 2.5	7 or 8	1 or 2	2 400	8
3 600	+1 – 2.5	7 or 8	1 or 2	4 800	8
4 800*	+1 – 2.5	7 or 8	1 or 2	4 800	8
7 200	+1 – 2.5	7 or 8	1 or 2	9 600	16
9 600*	+1 – 2.5	7 or 8	1 or 2	9 600	16
12 000	+1 – 2.5	7 or 8	1 or 2	19 200	32
14 400	+1 – 2.5	7 or 8	1 or 2	19 200	32
19 200	+1 – 2.5	7 or 8	1 or 2	19 200	32

Table 8/V.110 – Asynchronous user rates (*concluded*)

Data rate (bit/s)	Rate tolerance (%)	Number of data units	Number of stop elements	RA0/RA1 rate (bit/s)	RA1 rate (kbit/s)
24 000	+1 – 2.5	7 or 8	1 or 2	38 400	64
28 800	+1 – 2.5	7 or 8	1 or 2	38 400	64
38 400	+1 – 2.5	7 or 8	1 or 2	38 400	64
NOTE 1 – * indicates rate whose support is mandatory for universal TA.					
NOTE 2 – Number of data bits includes possible parity bits.					

5.3.3 Asynchronous-to-synchronous conversion (RA0)

The RA0 function is only used with asynchronous V-series interfaces. Incoming asynchronous data is padded by the addition of stop elements to fit the nearest channel rate defined by $2^n \times 600$ bit/s. Thus, a 7200 bit/s user data signalling rate shall be adapted to a synchronous 9600 bit/s stream and a 110 bit/s user data signalling rate shall be adapted to synchronous 600 bit/s stream. The resultant synchronous stream is fed to RA1. Padding with stop elements is inhibited during the transmission of the break signal as described in 5.3.5.

5.3.4 Overspeed/underspeed

A terminal adaptor shall insert additional stop elements when its associated terminal is transmitting with a lower than nominal character rate. If the terminal is transmitting characters with an overspeed of up to 1% (or 2.5% in the case of nominal speeds lower than 600 bit/s), the asynchronous-to-synchronous converter may delete stop elements as often as is necessary to a maximum of one every eight characters at 1% overspeed. The converter on the receiving side shall detect deleted stop elements and re-insert them in the received data stream (circuit 104).

The nominal length of the start elements and data units shall be the same for all characters. The length of the stop element may be reduced as much as 12.5% by the receiving converter for nominal speeds exceeding 300 bit/s to allow for overspeed in the transmitting terminal. For nominal speeds less than or equal to 300 bit/s, a 25% reduction in stop element is allowed.

5.3.5 Break signal

The terminal adaptor shall detect and transmit the break signal as follows:

If the converter detects M to $2M + 3$ bits, all of start polarity, where M is the number of bits per character in the selected format including start and stop elements, the converter shall transmit $2M + 3$ bits of start polarity.

If the converter detects more than $2M + 3$ bits, all of start polarity, the converter shall transmit all these bits as start polarity.

For the cases where the asynchronous rate is lower than the synchronous rate for the converter, the following rules shall apply:

- the converter shall transmit start polarity (to RA1) for a time period equal to $2M + 3$ bits at the asynchronous rate if the converter has detected M to $2M + 3$ bits of start polarity;
- the converter shall transmit (to RA1) start polarity for a time period as long as the received break condition if the converter has detected more than $2M + 3$ bits of start polarity;
- the $2M + 3$ or more bits of start polarity received from the transmitting side shall be output to the receiving DTE;

- the DTE must transmit on circuit 103 at least 2M bits of stop polarity after the start polarity break signal before sending further data characters. The converter shall then regain character synchronism from the following stop to start transition.

5.3.6 Parity bits

Possible parity bits included in the user data are considered as data bits by the RA0 function.

5.4 Flow control for use with TAs supporting asynchronous DTEs

A flow control option, for use with TAs supporting asynchronous DTEs, is described in this subclause. Flow control allows the connection of asynchronous DTEs operating at different user data rates by reducing the character output of the faster to that of the slower. Support of flow control will require the use of the end-to-end (TA-to-TA) protocol defined in 5.4.2 and an incoming line (from network) buffer in addition to a selected local protocol (see 5.4.1). Depending upon the local flow control protocol employed, there will also be a requirement for character buffering from the DTE interface. The size of this buffer is not defined in this Recommendation because it is dependent upon implementation. Criteria for buffer dimensioning may be found in Recommendation V.43.

Local flow control of the DTE interface is required where the DTE operates at a rate higher than the synchronous rate established between TAs. End-to-end flow control is required where the synchronous rate established between TAs is consistent with the operating rate of one DTE (or interworking unit) and higher than the synchronous rate consistent with the operating rate of the other DTE (or interworking unit). Both local and end-to-end flow control could be required in some applications.

5.4.1 Local flow control: between TA and DTE

Connection may be made between TAs connected to asynchronous DTEs operating at two different character rates. It is the responsibility of the TA connected to the faster DTE to execute a local flow control protocol to reduce the character rate to that of the slower DTE. This operation will require some buffer storage in the TA. A TA may support several different local flow control protocols, although only one will be selected at any one time. There are a number of such protocols in use, some of which are detailed in the following subclauses. DTE-DCE flow control mechanisms are described in detail in Recommendation V.43.

5.4.1.1 133/106 operation

This is a bidirectional (DCE and DTE control each other) out-of-band flow control mechanism, utilizing two of the interchange circuits specified in Recommendation V.24. A DCE not-ready condition is indicated by turning circuit 106 OFF and cleared by turning circuit 106 (ready for sending) ON. A DTE not-ready condition is indicated by an ON-to-OFF transition and cleared by an OFF-to-ON transition of circuit 133 (ready for receiving).

5.4.1.2 105/106 operation

This is a unidirectional (DCE controls DTE) out-of-band flow control mechanism, utilizing two of the interchange circuits specified in Recommendation V.24. If a DTE requires to transmit a character, it turns ON circuit 105 (request to send). The DTE can only begin transmission when it receives in return circuit 106 ON (ready for sending). If, during transmission of a block of characters circuit 106 goes OFF, the DTE shall cease transmission (after completing the transmission of any character of which transmission has started) until circuit 106 turns ON again.

NOTE – The apparent conflict between this and 7.1.2.4 (Note 1) and 7.1.3.1 a) is for further study.

5.4.1.3 XON/XOFF operation

This is an in-band flow control mechanism using two characters of the International Alphabet No. 5 (IA5) set for XON and XOFF operation. It may be used either unidirectionally (DCE controls DTE) or bidirectionally (DCE and DTE control each other). If a DTE (or DCE) receives an XOFF character, it shall cease transmission. When it receives an XON character, it may resume transmission. The characters typically used for XON and XOFF are device control one (DC1) and device control three (DC3) (bit combinations 1/1 and 1/3 in Recommendation T.50) respectively, although alternative bit combinations can be used.

5.4.1.4 Other methods

Alternative and non-standard methods of asynchronous flow control are in use, and these may be mapped onto the TA flow control protocol.

5.4.2 End-to-end (TA-to-TA) flow control

Matching (by reduction) of the transmitted character rate of the DTE to the rate of the TA is not sufficient in all cases to guarantee correct operation, and end-to-end flow control may be required.

The X-bit is used to carry flow control information. A TA will buffer incoming characters. When the number of buffered characters exceeds a threshold TH1, depending upon implementation, the TA will set the X-bit of its outgoing frames to OFF.

Upon receipt of a frame containing an X-bit set to OFF, a TA will execute its selected local flow control procedure indicating that the attached DTE must stop sending characters, and cease the transmission of data after completion of the character in progress by setting the data bits in the outgoing frames to ONE.

When the buffer contents of a TA which has initiated an end-to-end flow control drops below threshold TH2, the TA will reset the outgoing X-bit to ON.

When the far-end TA receives a frame with the X-bit set to ON, it will recommence data transmission, and, by use of the local flow control procedure, indicate to the attached DTE that it may continue.

NOTE – There may be a delay between initiation of the end-to-end flow control protocol and termination of the incoming character stream. The characters arriving during this time must be buffered, and the total buffer size will depend upon the character rate, round-trip delay and the buffer threshold.

5.4.3 Use of channel capacity

Upon accepting a call from a TA supporting flow control and operating at a different user rate and/or intermediate rate, the called TA will adopt the identical intermediate rate and bit repetition factor. This will override the parameters normally selected. In such cases, the TA connected to the faster DTE will execute a local flow control procedure to reduce the character rate to that of the slower DTE.

Thus, if a faster DTE calls a slower DTE, the faster intermediate channel rate and bit repetition factor will be adopted by the TAs on both ends. To reduce the character rate received by the slower DTE, its TA will exercise end-to-end flow control and cause the TA on the calling side to utilize local flow control.

If a slower DTE calls a faster DTE, the slower intermediate channel rate and bit repetition factor will be adopted by the TAs on both ends. To reduce the character rate transmitted by the faster DTE, its TA will exercise local flow control.

If the called TA does not implement the intermediate rate and bit repetition factor used by the calling TA, the call shall be rejected.

5.4.4 Requirements of a TA supporting flow control

The following are general requirements for a TA supporting flow control:

- i) A TA supporting flow control shall be capable of operating with an intermediate rate and bit repetition factor that is independent of the asynchronous speed used at its DTE interface.
- ii) A TA supporting flow control shall, if possible, adapt to the intermediate rate and bit repetition factor required for an incoming call. User rate information will be obtained from signalling.
- iii) A TA supporting flow control shall be capable of executing a local flow control protocol to reduce the character rate to that of the far-end DTE.
- iv) A TA supporting flow control will support the use of end-to-end (TA-to-TA) flow control using the X-bit, and will contain a character buffer.

6 Interchange circuits

6.1 Essential and optional interchange circuits

The essential and optional interchange circuits are listed in Table 9.

Table 9/V.110

Interchange circuit (Note 1)		
Number	Description	Notes
102	Signal ground or common return	
102a	DTE common return	2
102b	DCE common return	2
103	Transmitted data	
104	Received data	
105	Request for sending	3, 8
106	Ready for sending	
107	Data set ready	
108/1	Connect data set to line	4
108/2	Data terminal ready	4
109	Data channel received line signal detector	
113	Transmitter signal element timing (DTE source)	5
114	Transmitter signal element timing (DCE source)	
115	Receiver signal element timing (DCE source)	
125	Calling indicator	6
133	Ready for receiving	7, 8
140	Loopback/maintenance test	9
141	Local loopback	9
142	Test indicator	9

Table 9/V.110 (concluded)

NOTE 1 – All essential circuits and any others which are provided shall comply with the functional and operational requirements of Recommendation V.24. All interchange circuits provided shall be properly terminated in the data terminal equipment and in the data circuit-terminating equipment in accordance with the appropriate Recommendation for electrical characteristics (see 6.5).

NOTE 2 – Interchange circuits 102a and 102b are required where the electrical characteristics defined in Recommendation V.10 are used at data signalling rates above 20 kbit/s.

NOTE 3 – Not required for DTEs designed to operate with DCEs in the continuous carrier (duplex) mode and where in addition the DTE is not intended to exhibit out-of-band flow control (see 5.4).

NOTE 4 – This circuit shall be capable of operating as circuit 108/1 or 108/2, depending on its use (by the associated DTE).

NOTE 5 – The use of circuit 113 is for further study since its application is restricted by the synchronous nature of ISDN.

NOTE 6 – This circuit is used with the automatic answering terminal adaptor function.

NOTE 7 – Required for duplex DTEs that use bidirectional out-of-band (133/106) flow control.

NOTE 8 – Circuits 105 and 133 are assigned to the same connector pin on the standardized 25- and 26-pole connectors (ISO/IEC 2110 and ISO/IEC 11569). As circuit 133 is used only in duplex operation and circuit 105 is used only in half duplex operations, there should be no conflict.

NOTE 9 – The use for loopback testing is for further study.

6.2 Timing arrangement

The TA shall derive ISDN timing from the received bit stream of the ISDN's basic user/network interface (see clauses 5/I.430 and 8/I.430). This network timing shall be used by the TA to provide the DTE with transmitter signal element timing on circuit 114 and receiver signal element timing on circuit 115.

6.3 Circuit 106

After the start-up and retrain synchronization sequences, the ON state of circuit 106 shall be delayed relative to the ON state of circuit 105 (where implemented) by an interval of at least N bits (a value of N equal to 24 has been proposed, but the value is for further study). ON to OFF state transitions of circuit 106 shall follow ON to OFF state transitions of circuit 105 (when implemented) by less than 2 ms. Where circuit 105 is not implemented, the initial circuit 106 transition to the ON state shall be delayed by an interval greater than or equal to N bits relative to the corresponding transition in the state of circuit 109. Subsequent transitions in the state of circuit 106 should occur solely in accordance with the operating sequences defined in clause 7, or when used for the optional flow control defined in 5.4.

6.4 Circuit 109

OFF to ON and ON to OFF transitions of circuit 109 should occur solely in accordance with the operating sequence defined in clause 7.

6.5 Electrical/mechanical characteristics of interchange circuits

6.5.1 Basic ISDN user/network interface

The electrical and mechanical characteristics of the basic ISDN user/network interface are described in clauses 8/I.430 and 10/I.430.

6.5.2 TE2/TA (DTE/DCE) interface

6.5.2.1 Rates less than or equal to 19.2 kbit/s

Use of electrical characteristics conforming to Recommendations V.28 is recommended together with the connector and pin assignment plans specified by ISO/IEC 2110 and ISO/IEC 11569.

6.5.2.2 Rates greater than 19.2 kbit/s

Use of electrical characteristics conforming to Recommendations V.10 and/or V.11 is recommended together with the use of the connector and pin assignment plan specified by ISO 4902.

- i) Concerning circuits 103, 104, 113, 114 and 115, both the generators and the receivers shall be in accordance with Recommendation V.11.
- ii) In the case of circuits 105, 106, 107 and 109, generators shall comply with Recommendation V.10 or alternatively Recommendation V.11. The receivers shall comply with Recommendation V.10, category 1, or Recommendation V.11 without termination.
- iii) In the case of all other circuits, Recommendation V.10 applies, with receivers configured as specified by Recommendation V.10 for category 2.

NOTE – Equipment may be encountered that uses the interface defined in Appendix II of former Recommendation V.35 (withdrawn) together with the connector and pin assignment plan specified by ISO/IEC 2593.

6.6 Fault condition on interchange circuits

See clause 7/V.28 for association of the receiver failure detection types.

6.6.1 The DTE should interpret a fault condition on circuit 107 as an OFF condition using failure detection type 1.

6.6.2 The data circuit-terminating equipment (DCE) shall interpret a fault condition on circuits 105 and 108 as an OFF condition using failure detection type 1.

6.6.3 All other circuits not referred to above may use failure detection types 0 or 1.

7 Operating sequence

Four interoperational cases for a V.110 TA are described in A.4. This clause describes the operating sequence for a V-series TE2 (DTE) communicating with another V-series TE2 via V.110 TAs connected through the ISDN. This clause also applies to the V-series TE2 side of the other three interoperational cases.

The operating sequence is specified such that a pair of TAs connected via the ISDN shall exhibit behaviour (as observed at the DTE-DCE interfaces) that is equivalent to that exhibited by a pair of V-series modems interconnected via the PSTN.

For a TA communicating with an interworking function, the behaviour observed at the TA's DTE-DCE interface is equivalent to that exhibited by a V-series modem. The detailed operating sequence is for further study.

7.1 TA duplex operation

When using the TA to provide data transmission service within ISDN, the call is established over a 64-kbit/s connection using the procedures applicable to the particular network and/or terminal configuration.

The internal arrangement of the TA functional parts and the DTE (with a V-series type interface) is not within the scope of this Recommendation. It is assumed that means are provided to control the entry to and the exit from the data transfer mode. For example, it is assumed that the means are provided to control circuits 108/1 (Connect data set to line) or 108/2 (Data terminal ready) internally, that is within the station at the customer premises. However, for the purpose of this Recommendation circuit 108/2, as defined in Recommendation V.24, is assumed. In this subclause, the SA and SB groups of status bits are treated as a single sequence of S-bits.

NOTE – The operating sequence of a duplex V.110 TA has been specifically designed such that a V-series TE2 connected to the ISDN via a V.110 TA can interoperate with an X.21 TE2 connected via an X.30 TA.

The operating sequence described in this clause is illustrated in Figure 3.

7.1.1 Idle (or ready) state

7.1.1.1 During the idle (or ready) state the TA (DCE) will be receiving the following from the DTE:

- Circuit 103 = Continuous binary 1.
- Circuit 105 = See Note.
- Circuit 108/1 = OFF; circuit 108/2 = ON.

NOTE – In many duplex DTEs circuit 105 is either permanently in the ON condition or it is not present. If not present, the function must be set in an ON condition in the TA. See 7.1.2.4 for the case where a duplex DTE can operate circuit 105.

7.1.1.2 During the idle (or ready) state the TA will transmit continuous binary 1s into the B- and D-channels (i.e. all bits of Table 2 = binary 1).

7.1.1.3 During the idle (or ready) state the TA (DCE) will transmit the following toward the DTE:

- Circuit 104 = Continuous binary 1.
- Circuit 107 = OFF.
- Circuit 106 = OFF.
- Circuit 109 = OFF.

7.1.2 Connect TA to line state

7.1.2.1 When the TA is to be switched to the data mode, circuit 108 must be ON. Switching to the data mode causes the TA to transmit the following towards the ISDN (refer to Table 2):

- a) frame synchronization pattern as described in 5.1.3.1 and 5.2.1;
- b) data bits = binary 1;
- c) status bits S = OFF and X = OFF (ON = binary 0, OFF = binary 1).

NOTE 1 – At this time, circuit 103 is not connected to the data channel (e.g. the binary 1 condition of the data bits is generated within the TA).

NOTE 2 – In the following description only the inter-operation between TE2/TA (DTE/DCE) interface and the intermediate rate frames (see Tables 6a to 6f) and the 64 kbit/s frame of Tables 7a and 7c are discussed. The second step of rate adaption encoding and decoding and the multiplexing and demultiplexing of the ISDN basic user/network interface are discussed in Recommendations I.460 and I.430, respectively.

7.1.2.2 At this time (i.e. switching to data mode) the receiver in the TA will begin to search for the frame synchronization pattern in the received bit stream (see 5.1.3.1 and 5.2.1) and start timer T1. A suggested value is 10 s (see I.7.1).

7.1.2.3 When the receiver recognizes the frame synchronization pattern, it causes the S- and X-bits in the transmitted frames to be turned ON (provided that circuit 108 is ON).

7.1.2.4 When the receiver recognizes that the status of bits S and X are in the ON condition, it will perform the following functions:

- a) Turn ON circuit 107 toward the DTE and stop timer T1.

NOTE 1 – A duplex DTE that implements and is able to operate circuit 105 may be expected to turn this circuit ON at any time. However, if not previously turned ON, it must be turned ON in response to the ON condition on circuit 107.

- b) Then, circuit 103 may be connected to the data bits in the frame; however, the DTE must maintain a binary 1 condition on circuit 103 until circuit 106 is turned ON in the next portion of the sequence.

- c) Turn ON circuit 109 and connect the data bits to circuit 104.

NOTE 2 – Binary 1 is being received on circuit 104 at this time.

- d) After an interval of *N* bits (see 6.3), it will turn ON circuit 106.

- e) Circuit 106 transitioning from OFF to ON will cause the transmitted data to transition from binary 1 to the data mode.

If circuit 107 has not been turned ON, after expiring of timer T1 the TA shall be disconnected according to the procedures specified in 7.1.4.

7.1.3 Data transfer state

7.1.3.1 While in the data transfer state, the following circuit conditions exist:

- a) circuits 105 (when implemented), 107, 108/1 or 108/2 and 109 are in the ON condition;
- b) data is being transmitted on circuit 103 and received on circuit 104;
- c) circuits 133 (when implemented) and 106 are in the ON condition unless local out-of-band flow control is being used, in which case, either or both circuits may be in the ON or the OFF condition.

7.1.3.2 While in the data transfer state, the following status bit conditions exist:

- a) status bits S in both directions are in the ON condition;
- b) status bits X in both directions are in the ON condition unless end-to-end flow control is being used, in which case status bit X in either or both directions may be in the ON or the OFF condition.

7.1.3.3 While in the data transfer state, for the interoperational cases not involving an interworking function (IWF):

- a) the S status bits shall not be mapped to/from the interchange circuits according to Table 3;
- b) the X status bits shall not be mapped according to Table 3 unless end-to-end flow control is implemented.

NOTE – Certain equipment designed prior to the publication of this version of V.110 may map one or both of the S status bits to/from the interchange circuits according to Table 3.

The use of the S and X status bits in the data transfer state to carry status information to/from the modem in an IWF is for further study.

7.1.4 Disconnect mode

7.1.4.1 At the completion of the data transfer phase, the local DTE will indicate a disconnect request by turning OFF circuit 108. This will cause the following to occur:

- a) the status bits S in the frame toward ISDN will turn OFF, status bits X are kept ON;
- b) circuit 106 will be turned OFF;
- c) the data bits in the frame will be set to binary 0.

To guard against the failure of the remote TA to respond to the disconnect request, the local TA may start a timer T2 (suggested value 5 s) which is stopped by the reception or transmission of any D-channel clearing message (DISCONNECT, RELEASE, RELEASE COMPLETE). If the timer expires, the local TA should clear the call via the ISDN D-channel signalling protocol.

7.1.4.2 If circuit 108 is still ON at the remote TA, this TA will recognize the transition of the status bits S from ON to OFF and the data bits from data to binary 0 as a disconnect request and it will turn OFF circuits 107 and 109. This DTE should respond by turning OFF circuit 108 and transferring to disconnected mode. The disconnection will be signalled by the TA via the ISDN D-channel signalling protocol. At this time, the DTE/DCE interface should be placed in the idle (or ready) state.

7.1.4.3 The TA at the station that originated the disconnect request will recognize reception of S = OFF or the loss of framing signals as a disconnect acknowledgement and turn OFF circuits 107 and 109 and transfer to disconnected mode. The disconnection will be signalled by the TA via the ISDN D-channel signalling protocol. At this time, the DTE/DCE interface should be placed in the idle (or ready) state.

7.1.5 Loss of frame synchronization

In the event of loss of frame synchronization, the (local) TA should attempt to resynchronize as follows:

- a) Place circuit 104 in binary 1 condition (passes from the data mode).
- b) Turn OFF status bit X in the transmitted frame.
- c) The remote TA upon recognition of status bit X OFF will turn OFF circuit 106 which will cause the remote DTE to place circuit 103 in a binary 1 condition.
- d) The local TA should attempt to resynchronize on the incoming signal.
- e) If after an interval of three seconds the local TA cannot attain synchronization, it should send a disconnect request by turning OFF all of the status bits for several (at least three) frames with data bits set to binary 0 and then disconnect by turning OFF circuit 107 and transferring to the disconnected mode as discussed in 7.1.4.2.

NOTE 1 – The values of three seconds and three frames are provisional and should be confirmed or amended after further study.

- f) If resynchronization is achieved, the local TA should turn ON status bit X toward the distant station.
- g) If resynchronization is achieved, the TA (which has turned OFF circuit 106) should, after an interval of *N* bits (see 6.3), turn ON circuit 106. This will cause circuit 103 to change from binary 1 to the data mode.

NOTE 2 – During a resynchronization attempt, circuits 107 and 109 should remain ON.

7.2 TA half-duplex operation

The data call establishment for the interworking of half-duplex DTEs equipped with V-series type interfaces is the same as discussed in 7.1. The only difference between half-duplex operation is in the control of the circuits 105, 106, and 109, as follows.

NOTE – This is a unique application; therefore, TA arranged for half-duplex operation will not be able to interwork with either a V-series or an X-series duplex DTE (TE2).

7.2.1 In a TA arranged to accommodate half-duplex DTEs, circuit 109 will be under the control of the status bits SB in the incoming frame, as follows:

- a) If at the local interface circuit 109 is OFF and circuit 104 is in the binary 1 state, the DTE may "request to send" by turning ON circuit 105.

- b) The TA will then turn ON status bits SB in the transmitted frame which will at the remote interface turn ON circuit 109 and connect circuit 104 to the data bit stream of the incoming frame.
- c) After an N bit interval (see 6.3) the local TA will turn ON circuit 106, which will allow the local DTE to transmit data on circuit 103.
- d) Upon completion of the transmission, the local DTE will turn OFF circuit 105. This will in turn:
 - turn OFF circuit 106 at the local interface, and circuit 103 will revert to the binary 1 state;
 - turn OFF status bits SB which will in turn at the remote TA turn OFF circuit 109 and place circuit 104 in a binary 1 condition.
- e) At this time the remote DTE is able to reverse the sequence by turning ON circuit 105.

7.3 Automatic calling

The mapping of V.25 *bis* automatic calling and automatic answering procedures to the ISDN D-channel signalling protocols is described in Appendix II.

8 Network-independent clocks

In cases where synchronous data signals at user rates up to and including 19.2 kbit/s are received from outside the ISDN (e.g. through an interworking unit from a DTE/modem on the PSTN), the data may not be synchronized to the ISDN. Such a situation would exist where the signals are received through an interworking unit from voiceband data modems on the analogue PSTN, where the transmit data from the remote modem is synchronized to the modem clock (normal case for such applications). The frequency tolerance of such modems is 100 ppm. The following method shall be used to enable transfer of those data signals and the corresponding bit timing information via the 80-bit frame to the receiving TA.

8.1 Measurement of phase differences

The phase difference between the following two frequencies will be measured:

- i) $R1 = 0.6 \times$ the nominal intermediate rate (except where Fill bits are used; see Note), synchronized with the ISDN;
- ii) $R2 = 0.6 \times$ the nominal intermediate rate (except where Fill bits are used; see Note), derived from and synchronized with the bit timing received from the remote synchronous source, e.g. modem.

NOTE – Clocks R1 and R2 are nominally either 4800, 9600 or 19 200 Hz at 8 kbit/s, 16 kbit/s and 32 kbit/s intermediate rate, respectively.

Where Fill bits are used, in the cases of 7200 and 14 400 bit/s R1 and R2 will have the same nominal rate as the user bit rate.

Compensation will affect one, one-half, one-quarter or one-eighth of a user data bit, dependent upon the bit repetition factor.

A state diagram for the transmitting TA showing the phase of R2 relative to R1 appears in Figure 5. Table 10 shows the related bit coding.

NOTE 1 – Phase measurements are given relative to R1 by the formula: Phase = phase (R2) – phase (R1).

NOTE 2 – Receipt of a bit combination requiring an illegal move of more than one state will cause a legal move of one state in the appropriate direction.

NOTE 3 – The initial state of both the receiving and transmitting sides of the TA will be 0%.

Figure 5/V.110 – Network-independent clocking state diagram

Comparison of R1 and R2 will give a phase difference relative to R1 which will be encoded as shown in Table 10. The resultant 3-bit code will be transmitted in bit positions E4, E5 and E6, and used for clock control at the receiving TA.

Table 10/V.110 – Coding of E-bits for network-independent clocking

Displacement (in % of nominal R1 clock period at $n \times 4800$ bit/s, $n = 1, 2$ or 4)	Coding in the 80-bit frame		
	E4	E5	E6
Nominally 0	1	1	1
+20	0	0	0
+40	0	0	1
-40	0	1	0
-20	0	1	1
Compensation control			
Positive compensation of a one	1	0	1
Positive compensation of a zero	1	0	0
Negative compensation	1	1	0

To avoid continuous jitter between neighbouring displacement positions, hysteresis shall be applied, as follows:

The displacement code shall be changed only when the measured phase difference between R1 and R2 is 15% (of the R1 clock period) more or less than the difference indicated by the existing displacement code.

Example – Bit combination 000 indicates a phase difference of nominally 20%. This bit combination will be changed into 001 when the measured phase difference is 35% or more, and into 111 when the measured phase difference is 5% or less.

8.2 Positive/negative compensation

On transition from the +40% state to the -40% state, an extra user D-bit has to be transmitted in the 80-bit frame, using bit E6 (positive compensation). At the receiving TA, this extra bit will be inserted between D24 and D25 as shown in Table 2, immediately following the E-bits.

On transition from the -40% state to the +40% state, a bit combination is transmitted in the 80-bit frame (E4, E5 and E6 = 1, 1, 0, respectively), indicating to the receiving TA that bit D25 of the 80-bit frame, being set to ONE, does not contain user data and should be removed (negative compensation).

8.3 Encoding

The encoding of the measured phase difference for clock control and the positive/negative compensation control overrides and replaces the clock control coding.

9 In-band parameter exchange state

The capabilities provided and operation in an optional in-band parameter exchange state are described in Appendix I.

10 Testing facilities

The provision of maintenance test loops is for further study, taking in consideration Recommendations X.150 and V.54.

ANNEX A

Reference configurations

A.1 Introduction

Figures A.1 and A.2 show the two basic reference models used in the development of this Recommendation, and provide valuable examples of the way in which the terminal adaptor may be used. These are provided simply as an aid to the interpretation of this Recommendation and should not be seen as restrictive in any way.

A.2 V.110 terminal adaptor reference model

Figure A.1 shows the basic reference model for a V.110 terminal adaptor.

NT Network Termination

TE2 Data terminal equipment (DTE) with an interface complying to Recommendation V.24

(1) R interface functions (according to Recommendations V.24, V.28, etc.)

(2) Specific TA functions (e.g. data rate adaption)

(3) Control access signalling function (e.g. signalling in accordance with Recommendations Q.921 and Q.931, auto calling in accordance with Recommendation V.25 *bis*)

(4) S/T interface layer 1 functions (according to Recommendation I.430)

Figure A.1/V.110 – Terminal adaptor reference model

The elements (1), (2), (3) and (4) shown in Figure A.1 represent the functionality required of a terminal adaptor. The elements are not intended to correspond to separate physical units. However, a terminal adaptor need not necessarily constitute a single physical unit. The functions of these elements are:

- 1) Provision of layer 1, in accordance with Recommendations V.24 and V.28 or other applicable Recommendations and ISO/IEC 2110 or other applicable standards, of the interface at reference point R.
- 2) Specific TA functions, including the adaption of the TE2 data (rate and format) for transmission over an ISDN B-channel and provision of R-interface lead control information. This Recommendation covers primarily these functions.
- 3) Network control signalling functions, including the mapping of call control signals (in accordance with Recommendation V.25 *bis* or other applicable standard) at the R-interface into signals (according to Recommendation Q.931) for transmission on the D-channel across the S/T interface.
- 4) Provision of layer 1, in accordance with Recommendation I.430 of the interface at reference points S or T.

A.3 Terminal adaption type

A.3.1 Terminal adaptor – Type A (TA-A)

The TA-A provides manual call control functions and the functions necessary for data transfer. The following data transfer functions are included:

- a) Conversion of electrical, mechanical, functional and procedural characteristics of the V-series type interface(s) to those required by an ISDN at reference points S and/or T, as discussed in 6.5;
- b) Bit rate adaption of the V-series data signalling rates to the 64-kbit/s B-channel rate as described in 5.1, 5.2 and 5.3;
- c) End-to-end synchronization of entry to and exit from the data transfer phase, as described in clause 7.

Terminal adaptor TA-A may be implemented using a physically separate TE1 for providing the network control signalling function, unit (3) in Figure A.1, or the function may be part of an integrated implementation. The function provides for data connection establishment when using the circuit-mode 64-kbit/s unrestricted bearer service. The function includes provisions for speech and data connection establishment when using for speech, both circuit-mode 64-kbit/s bearer service usable for 3.1-kHz audio information transfer, and, for data, the circuit-mode 64-kbit/s unrestricted bearer service concurrently on two B-channels.

A.3.2 Terminal adaptor – Type B (TA-B)

The TA-B includes, in addition to those functions provided by a TA-A, the mapping functions necessary to convert the automatic calling and/or automatic answering procedures of Recommendation V.25 *bis* to the ISDN D-channel signalling protocol. This additional functionality is in functional unit (3) in Figure A.1. Terminal adaptor type B is to be used with the 64-kbit/s unrestricted bearer service.

The need for provisions covering functional unit (3) in Figure A.1 for the implementation of a type B-terminal adaptor is for further study.

NOTE – Reference to the use of the term "unrestricted bearer". During an interim period, some networks may only support restricted 64-kbit/s signal digital information transfer capability, i.e. information transfer capability solely restricted by the requirement that the all-zero octet is not allowed. Such networks may offer bearer services with restricted transport capabilities.

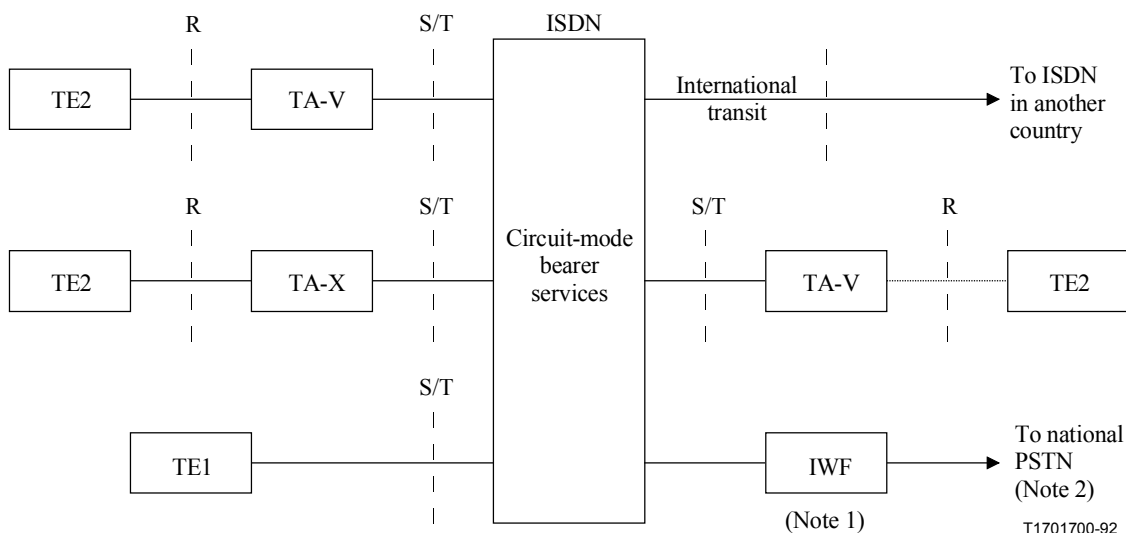

A.4 Types of end-to-end connection

The terminal adaptor functions described in this Recommendation take into account the end-to-end connection types shown in Figure A.2. The figure shows the interoperational cases considered in this Recommendation, as follows:

- V-series TE2 with V-series TE2;
- V-series TE2 with X.21 TE2;
- V-series TE2 with TE1;
- V-series TE2 with V-series DTE on the PSTN through an interworking function (IWF).

NOTE – The adaption of terminals by the connection of modem-equipped TE2s to the analogue side of a CODEC to provide for the use of 3.1-kHz bearer capabilities is not addressed in this Recommendation.

Interworking with PSTNs may be provided on the basis of a trunk interconnection using interworking functions (IWFs) (see Note 1 of Figure A.2). The reference connections illustrated in Figure A.2 do not envisage a direct connection between an ISDN in one country and a public switched telephone network (PSTN) in another country via a network-provided interworking function in the first country. However, access to non-ISDN countries could be through the normal PSTN international connections.

IWF Interworking function

TA-V Terminal adaptor function – (DTEs with V-series interfaces)

TA-X Terminal adaptor function – (DTEs with X.21 or X.21 *bis* interfaces). See Recommendation X.30.

NOTE 1 – The location of this interworking function is discussed in Recommendation I.510 and general requirements are given in Recommendations I.515 and I.530. The need for a Recommendation covering detailed requirements for such an IWF is for further study.

NOTE 2 – For access to national non-ISDN terminals or international access to PSTNs of non-ISDN countries.

Figure A.2/V.100 – Network reference connections

APPENDIX I

In-band parameter exchange

I.1 Introduction

During the evolution of ISDN there will exist for a considerable period:

- DTEs with V-series type interfaces which are to be connected to an ISDN by terminal adaptors; and
- requirements for interoperation between DTEs/TAs connected to ISDNs, that are interconnected with facilities which do not provide for the full ISDN out-of-band signalling capability necessary to support parameter exchange between terminal adaptors.

Considering that Recommendation I.530 defines interworking between an ISDN and a PSTN in general, that Recommendation I.515 describes the parameter exchange for interworking between ISDNs and existing networks, the specific procedure to be used for in-band parameter exchange (IPE) within the context of terminal adaptors following this Recommendation is as described in this appendix. This procedure is consistent with Recommendations I.530 and I.515.

It enhances the capability of V.110 TA in order to support:

- the transfer of the end-to-end information required for the compatibility checking of data calls;
- an exchange of terminal adaptor parameter information; and
- an exchange of information related to maintenance operations.

I.2 Definitions

For the IPE, which is described in this appendix, the following definitions apply. These definitions are ordered logically to minimize forward referencing.

I.2.1 TA: A terminal adaptor.

I.2.2 calling TA: The TA requesting the connection to be established.

I.2.3 called TA: The TA accepting the connection.

I.2.4 originating TA: The TA which is responsible for initiating the next exchange of parameter information. Initially, the calling TA takes on the role of the originating TA.

I.2.5 answering TA: The TA which is not responsible for initiating the next exchange of parameter information. Initially, the called TA takes on the role of the answering TA.

I.2.6 parameter information: Terminal adaption protocol information, TA parameters, and (optionally) maintenance information.

I.2.7 parameter block: The complete set of parameter information structured into message groups which are transferred by each TA towards the other during each parameter exchange.

I.2.8 message group: The arrangement of octets based on a repeated sequence of command octets followed by a series of three LOW-HIGH data octet pairs. Each message group transfers one octet of the parameter information.

I.2.9 sequence of command octets: The repeated transmission of at least 32 command octets transmitted without interval for 64-kbit/s unrestricted and restricted channels. In the case of asynchronous IPE the sequence may be interrupted, within the limits of the procedures.

I.2.10 series of LOW-HIGH data octet pairs: The transmission of six octets grouped into three pairs of LOW-HIGH data octets, the LOW data octet being transmitted in each pair before the HIGH data octet. The six octets are transmitted without interval for 64-kbit/s unrestricted and restricted channels. In the case of asynchronous IPE, the transmission of the six octets may be interrupted, within the limits of the procedures.

I.2.11 verification: Establishment of the validity of a piece of data according to the specified error handling procedures.

I.3 Overview

The in-band parameter exchange (IPE) described in this appendix is based on the transfer of parameter information within the user data stream of an established connection. Specific IPE rates have been selected to cover the application of IPE to connections based on 64-kbit/s unrestricted channels, 64-kbit/s restricted channels and intermediate rate channels. For IPE at rates other than 64 kbit/s, rate adaption according to this Recommendation is applied to the user data stream containing the parameter information.

In the case of IPE within intermediate rate channels, it is first necessary to achieve frame synchronization according to this Recommendation before the exchange can commence. The parameter information is transferred in a parameter block during one or more exchanges between the two TAs. The block structure is based on message groups, containing a sequence of command octets which identify the information carried in the message group, and a series of general purpose LOW-HIGH data octet pairs which carry the information. The command octets are always transmitted in a repeated sequence of at least 32 octets to allow persistency error handling techniques to be employed. The LOW-HIGH data octet pairs are always transmitted in a series of three to enable majority voting error recovery techniques to be used.

After the first exchange of parameters, the called TA determines whether the parameter exchange has been successful. If it is, both TAs proceed to the data transfer state directly unless the agreed data transfer rate first requires re-synchronization to a new intermediate rate according to this Recommendation. After the first exchange, and each subsequent exchange, the responsibility for determining the success of the exchange is transferred, to allow the negotiation of parameters to progress evenly. Status information is also transferred during the IPE to enable both TAs to monitor the progression of the exchange. If at any time either TA concludes that a successful exchange of parameters cannot be achieved, the TA should clear the connection.

Interworking with TAs not supporting IPE is specified.

I.4 Reference configuration

Figure I.1 gives an example of a scenario for an IPE procedure. It illustrates the connection of ISDNs using the connectivity of existing networks. As the evolution towards an ubiquitous international ISDN capability proceeds, the connection of ISDN islands will often use existing network capabilities. Two alternatives are indicated in Figure I.1. Either arrangement indicated may exist though the use of "digital connectivity" based on the existing integrated digital network (IDN) has many advantages including the avoidance of the need for layer 1 interworking functions. The IDN, however, does not have the ISDN signalling capability and this leads to the need for an IPE procedure. The IPE capability is required to enable communicating TAs to exchange parameters as well as to perform other operations such as maintenance functions. Even where the ISDN signalling capability is available, the IPE capability may be used to provide enhanced parameter exchange.

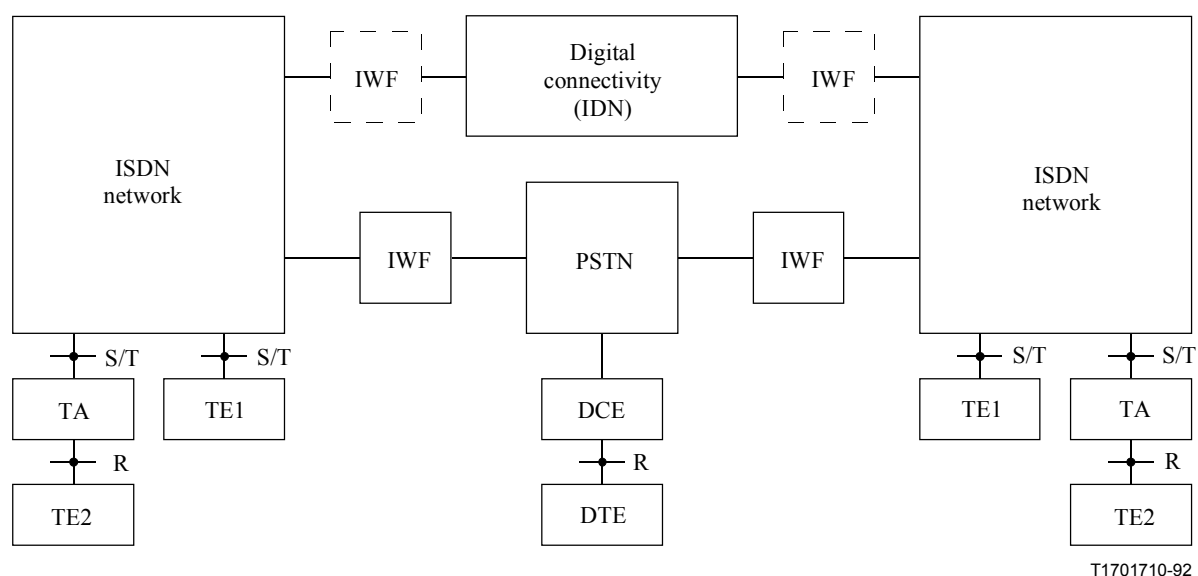

Figure I.1/V.110 – Reference configuration

I.5 Procedures

I.5.1 General

Subclause I.5 describes the procedures which permit a TA to exchange parameter and maintenance information in-band by using messages within the user data stream.

Once the call has been established, the IPE is initiated at one of four user data rates as per Table I.1. It is recommended that, where possible, the IPE is performed using the unrestricted/restricted 64 kbit/s rate. If the TA is not capable of starting at this rate, then the appropriate default

intermediate rate is used. Default intermediate-rate channels are selected according to this Recommendation for single stream operation described in Recommendation I.460. Subrate multiplexing cannot be supported until the IPE is complete.

The final rate of data transfer is not restricted by the choice of IPE user rate. (See Table I.1.) It is therefore possible for an IPE at 4.8 kbit/s async, for example, to agree on the use of 64 kbit/s unrestricted during the data transfer state. For IPE at rates other than 64 kbit/s, rate adaption according to this Recommendation is applied to the user data stream containing the IPE information. In order to prevent unintended disconnection when rate adaption according to this Recommendation is used, it is necessary to avoid the condition S = OFF, X = ON and all the data bits set to ZERO. This is achieved by the use of asynchronous characters with one stop bit and the permanent setting of bit 8 in all octets to ONE.

Table I.1/V.110 – Selection of IPE user rate

IPE intermediate rate	IPE data rate
Unrestricted/restricted (64 kbit/s)	56 kbit/s
32 kbit/s intermediate-rate channel	19.2 kbit/s async
16 kbits/s intermediate-rate channel	9.6 kbit/s async
8 kbits/s intermediate-rate channel	4.8 kbit/s async

Subclause I.5.2 describes how IPE is initiated, with the procedures for IPE itself described in I.5.3. If the parameter exchange results in the selection of a data rate based on a different intermediate rate to that used for IPE, re-synchronization is required. The procedures for re-synchronization and data transfer are given in I.5.4 and I.5.5 respectively. In I.5.6, the procedures for interworking with a TA not supporting IPE are given. In I.5.7 the procedures associated with maintenance are described. Subclause I.5.8 defines re-entry to IPE from the data transfer state, and I.5.9 provides the procedures for error protection and handling. Message codings are given in I.6, timer values in I.7 and state transition diagrams in I.8.

I.5.2 Initiating the exchange

An IPE TA requires a local memory flag (the re-entry flag) to control the re-entry into IPE from the data transfer state.

During the inactive state, the TA shall transmit continuous ONES into the B-channel (see I.8). Once a connection has been established, both TAs will initiate the parameter exchange at the selected user rate and set the re-entry flag to ZERO. Before beginning the parameter exchange, both TAs start timer T2 and may send repeated IDLE status octets (see I.6.5).

In the case where the TAs operate on a different IPE user rate, the following procedure shall be applied:

- during the first half of period T2, the called TA only tries to adapt to the IPE rate of the calling TA before transmitting its initial exchange of information;
- during the second half of period T2, the calling TA only tries to adapt to the called TA, and retransmits the initial exchange of information at the called TA user rate.

If timer T2 expires before a complete parameter block has been received, both TAs shall begin data transfer using their default parameters.

In the case of user rates of 4.8, 9.6 or 19.2 kbit/s, the TA first completes the frame synchronization procedure described in this Recommendation, with the changes detailed below:

- a) The transmitter sends frames towards its peer with status information S = OFF and X = OFF and enters the awaiting synchronization-parameter exchange state (state 6).
- b) When the TA recognizes the frame synchronization pattern in the awaiting synchronization-parameter exchange state (state 6), it verifies the status information received and then enters the appropriate state, in a coordinated manner, as follows:
 - Data transfer (state 4), upon receipt of S = ON and X = ON (see I.5.6);
 - IPE default exchange (state 5), upon receipt of S = OFF and X = OFF;
 - Parameter exchange (state 7), upon receipt of S = OFF and X = ON (see I.5.3).
- c) When the TA is in the IPE default exchange state (state 5), it shall transmit frames with status information S = OFF and X = ON and verify the status information received and then enter the appropriate state, in a coordinated manner, as follows:
 - Data transfer (state 4), upon receipt of S = ON and X = ON (see I.5.6);
 - Parameter exchange (state 7), upon receipt of S = OFF and X = ON (see I.5.3).

In the case of user rates of 56 or 64 kbit/s, there is no frame synchronization requirement.

I.5.3 Parameter exchange

I.5.3.1 Octet alignment

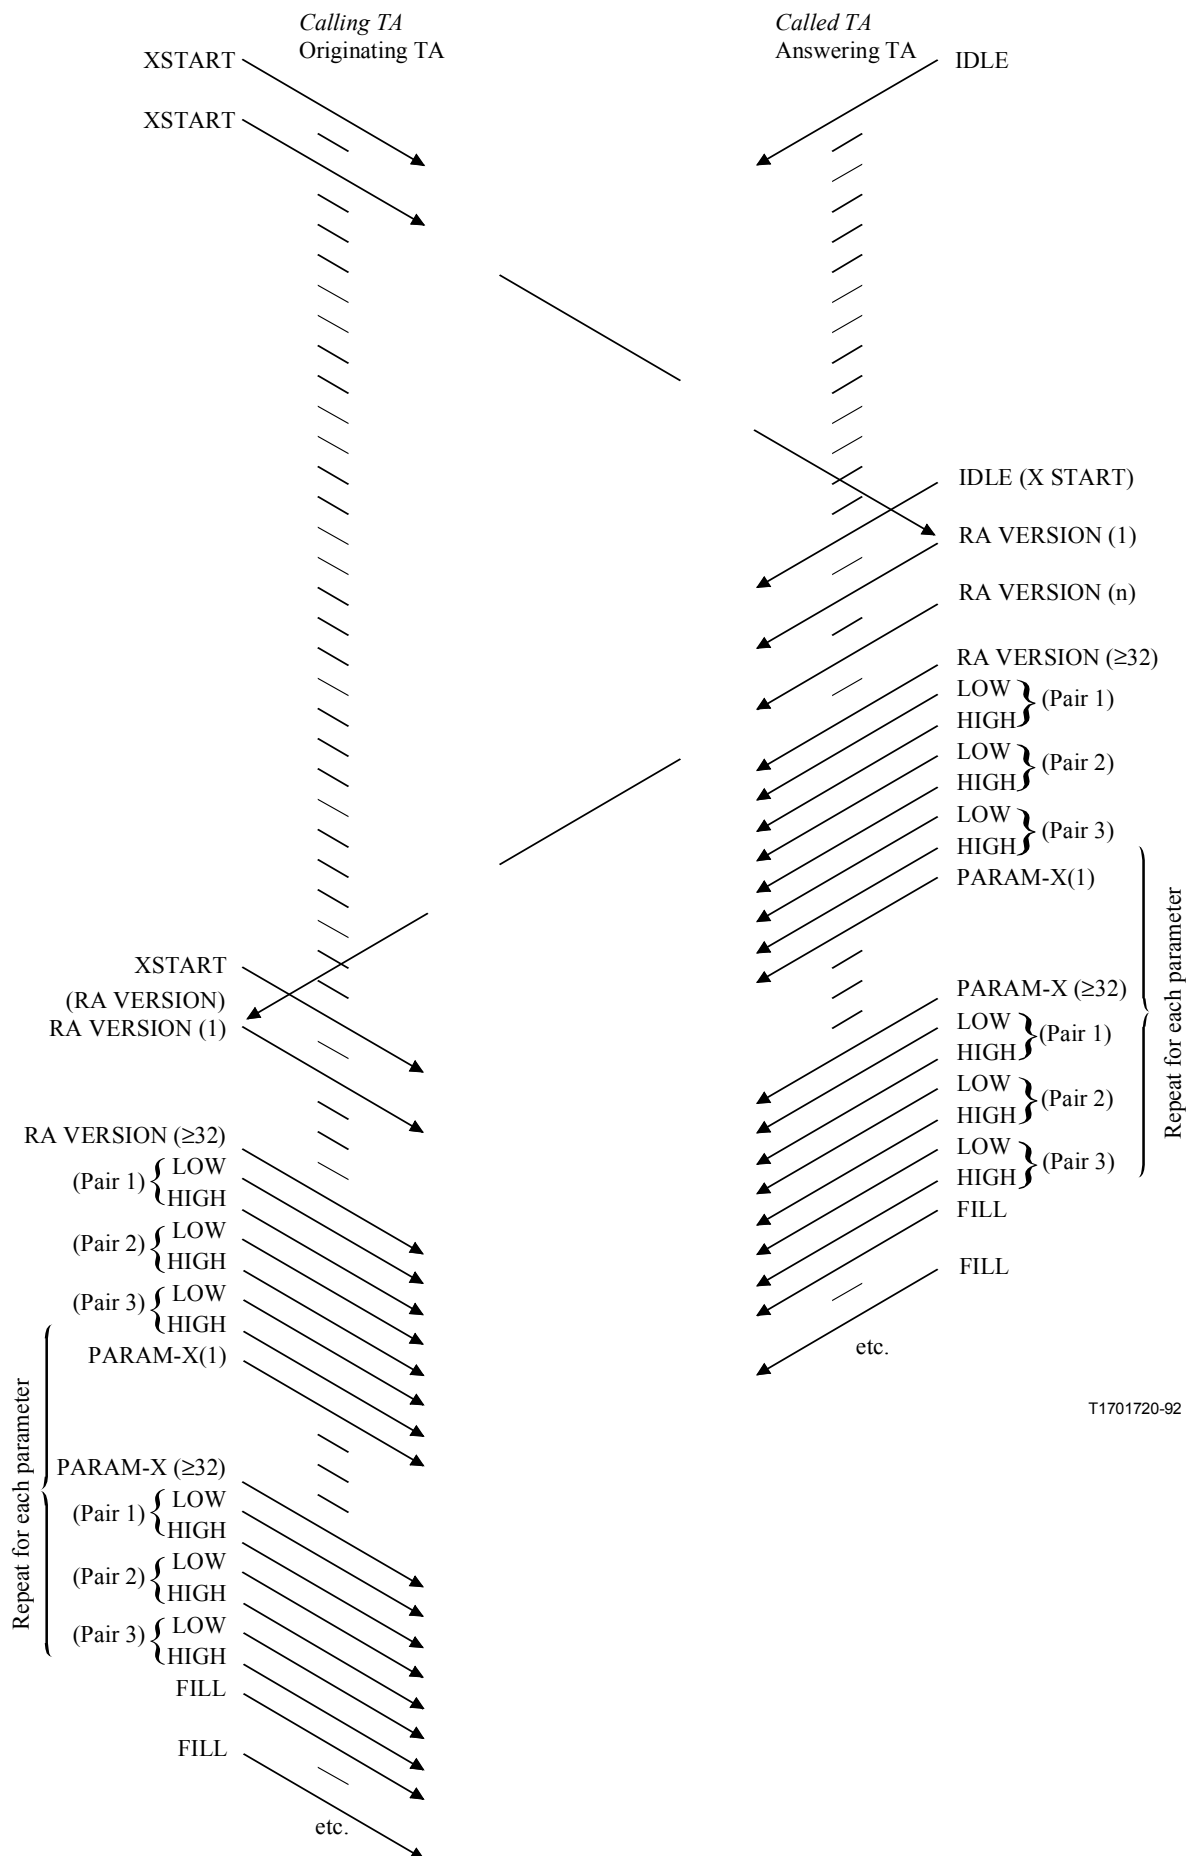

In the case of user rates of 4.8, 9.6 or 19.2 kbit/s, each octet of the parameter exchange message is carried as a single start-stop character (see I.6.1). In the case of user rates of 56 or 64 kbit/s, network-provided octet alignment shall be used.

I.5.3.2 Transfer of parameters

The correct interpretation of this subclause requires careful adherence to the definitions made in I.2, particularly for the meaning of a "sequence of command octets" (I.2.9) and a "series of LOW-HIGH data octet pairs" (I.2.10). Further detailed information is given in I.5.9 and I.6.

After the connection has been established, the calling TA takes on the role of the originating TA and the called TA the role of the answering TA.

The originating TA begins by starting timer T1 and transmitting a sequence of XSTART command octets (see I.6.3). After verifying the receipt of the XSTART command octets, the answering TA starts Timer T1 and begins parameter transfer as described below. Once the originating TA has verified the receipt of the RA VERSION command octet (at the start of the parameter transfer) from the answering TA, the originating TA also begins parameter transfer in the same manner. Figure I.2 portrays the normal sequence of events during the parameter exchange.

T1701720-92

Figure I.2/V.110 – Initial sequence of events during a parameter exchange

The parameter transfer commences with the transmission of a sequence of RA VERSION command octets followed by a series of LOW-HIGH data octet pairs containing the rate adaption identifier (see I.6.2). Directly following the transmission of the rate adaption identifier, the transfer continues with the parameters themselves in five groups: PARAM-0 to PARAM-4 (see I.6.4), transmitted in ascending order. Each group begins with the transmission of a sequence of the appropriate PARAM command octet followed by a series of LOW-HIGH data octet pairs which carry the parameters. At the completion of the parameter information transfer, both TAs send repeated FILL status octets until the next stage of the parameter exchange. Transmission of the complete parameter block shall be made within the period T2.

After receiving and processing the rate adaption and parameter information, the answering TA determines whether the parameters exchanged in both directions are compatible, or whether it can adapt to the parameters of the originating TA. In either case, the exchange has been successful and the procedures described in I.5.3.3 are followed. If the parameters were not compatible and the answering TA decides to continue, it now takes on the role of the originating TA and recommences the parameter exchange with the transmission of a sequence of XSTART command octets. The parameter transfer procedures therefore continue as described above, but with the roles of originating and answering carried out by the opposing TAs. In the first exchange, the called TA should attempt to adapt to the parameters of the calling TA. When continuing the exchange, the new originating TA should attempt, as far as possible, to move the values of its next transmitted parameters towards the values of those previously received. If either TA determines that there is no point in continuing the parameter exchange, the procedures described in I.5.3.4 are followed.

Parameter information continues to be exchanged in this manner, with alternate reversal of the roles of originating and answering TA until the outcome is successful, unsuccessful, or timer T1 expires.

In order that the service offered is not degraded from that provided without IPE, a TA should connect using its default parameters upon expiry of timer T1. This does not prohibit either TA initiating disconnection at any time.

I.5.3.3 Successful exchange

A parameter exchange is considered successful when the last set of TA parameters transferred in both directions are compatible, or when the answering TA can adapt to the parameters of the originating TA. The answering TA shall notify the originating TA of a successful exchange before proceeding; this notification is provided by the transmission of a sequence of READY status octets. Both TAs shall set the re-entry flag to ONE. In any case, both TAs will proceed into the data transfer state (see I.5.5.1) unless re-synchronization to a new intermediate rate is required (see I.5.4).

I.5.3.4 Unsuccessful exchange

If at any time during the exchange either TA concludes that a successful exchange of parameters cannot be achieved or that the rate adaption protocols are not compatible, the TA should clear the connection.

I.5.4 Re-synchronization to a new intermediate rate

If the outcome of the IPE is the selection of a user data rate requiring a new intermediate rate, re-synchronization will be necessary, and the TA enters the awaiting re-synchronization state (state 8). Whilst in this state the transmitter of the TA will send frames with S = OFF and X = OFF towards the peer TA in the new intermediate rate channel agreed. The default intermediate-rate channel positions correspond to those recommended for single stream operation in Recommendation I.460.

At the same time, the receiver of the TA will commence searching for the frame synchronization pattern in the selected sub-rate channel. When the TA recognizes the frame synchronization pattern, it shall verify the status information received and enter the appropriate state, in a coordinated manner, as follows:

- Data transfer (state 4), upon receipt of S = ON and X = ON (see I.5.6);
- No exchange (state 9), upon receipt of S = OFF and X = OFF.

When the TA is in the no exchange state (state 9), it shall transmit frames with status information S = ON and X = ON and enter the data transfer state (state 4) upon receipt of S = ON and X = ON.

I.5.5 Data transfer

I.5.5.1 Transition into the data transfer state

Entry into the data transfer state should be carried out in a coordinated manner, as described by this Recommendation by both TAs after sufficient time has been given to enable the processing of the parameter information.

I.5.5.2 The data transfer state

The procedures on entering the data transfer state (state 4) and the values of S and X status information in the case of data rates less than 56 kbit/s are described in this Recommendation.

I.5.6 Interworking with a TA not supporting IPE

A TA may choose to bypass IPE; for example, when it is used in a pre-configured arrangement, or when the parameter exchange can be effected by out-of-band signalling. In this situation a TA supporting IPE may receive S = ON and X = ON verified status information, causing the TA to directly enter the data transfer state. See I.8.

A TA not supporting IPE can receive frames containing the status information S = OFF and X = ON from its peer. In this situation the non-IPE TA may either continue to transmit the status information S = OFF and X = OFF, or change to the data transfer state and transmit the status information S = ON and X = ON. Both cases will lead to entry into the data transfer state without IPE. See I.8.

In the case of IPE at 64 kbit/s unrestricted or restricted, or in the case of a TA continuing to transmit the status information S = OFF and X = OFF, timer T2 ensures that service is not degraded from that provided without IPE. See I.8.

I.5.7 Maintenance

A TA maintenance (MNT) call is made by indicating in PARAM-0 that the calling TA requires MNT support and by directly following the parameter transfer with a MAINTENANCE message group identifying the function required (see I.6.6). A TA which supports MNT shall indicate in PARAM-0 that MNT support is available. When an MNT function is requested by a calling TA, the called TA capable of supporting MNT shall acknowledge the request by initiating a subsequent parameter exchange including at the end the identical MAINTENANCE message group, before continuing directly to invoke the required MNT function.

A successful MNT call with no timer required is terminated by either TA clearing the call. A successful MNT call with timer required returns the called TA to the inactive state upon expiry of timer T3, or to the Null state upon disconnection.

A TA which does not support MNT shall indicate in PARAM-0 of the initial exchange that no MNT support is provided, and should clear the connection after the initial parameter exchange when an MNT call is received.

I.5.8 Re-entering IPE from the data transfer state

Test loopbacks in this Recommendation refer to the I.600 series. The major application of this facility is to provide a mechanism to allow a remote loopback to be established for maintenance purposes without disconnecting the equipment in the established path. This mechanism may also be used generally to re-enter IPE.

This mechanism is not applicable to unrestricted 64-kbit/s or restricted 64-kbit/s connection types, or when the rate during data transfer is 64 kbit/s, 56 kbit/s or 48 kbit/s.

If re-entry to IPE is required and the re-entry flag has the value ONE, then the initiating TA enters the awaiting re-entry to IPE state (state 10) and transmits S = OFF, X = ON and D = IDLE. Re-entry to IPE in order to set a test loop 4 shall only be initiated by a calling TA.

Receipt of S = OFF, X = ON and D = IDLE shall cause a TA in state 4 to re-enter the parameter exchange state (state 7) at the IPE user rate defined in I.5.1 which is of the same intermediate rate as that used for data transfer.

Receipt of S = OFF, X = ON and D = IDLE shall cause the initiating TA to re-enter the parameter exchange state (state 7) at the IPE user rate defined in I.5.1 which is of the same intermediate rate as that used for data transfer.

I.5.9 Error protection and handling

Error protection and handling are required to overcome the possibility of data corruption. In addition, error recovery procedures are required, for example in the case of loss of frame synchronization.

To protect against data corruption, IPE commands shall be sent in a repeated sequence of at least 32 octets. Verification of the correct receipt of a command octet can then be carried out based on persistence checking techniques. Once a verified command octet has been received, it can be identified by the codings given in I.6. Any command octet not recognized shall be ignored. To protect against data corruption, LOW-HIGH data message pairs shall be sent in groups of three pairs. This enables majority voting techniques to be employed by the receiving TA.

Upon the detection of irrecoverable data corruption during the parameter exchange, loss of frame synchronization or other situations requiring the exchange to be restarted, the TA shall complete the current message flow and initiate error recovery by transmitting a sequence of XSTART command octets and assuming the role of the originating TA. Upon receipt of a sequence of XSTART commands octets, a TA will recommence the parameter exchange as described in I.5.3.2. In this case of a collision of XSTART octets, the original originating and answering roles are assumed by the TAs.

I.6 Coding

I.6.1 General

Information transfer during IPE is based on a group of messages. These messages are used to carry out a variety of tasks. The messages associated with rate adaption identification are described in I.6.2, whilst those associated with the actual parameter transfer are given in I.6.4. The messages associated with the control of the IPE are described in I.6.3, and I.6.5 covers those used to indicate status. Finally, I.6.6 covers the coding of the maintenance message.

The messages are all based on octets structured as shown in Figure I.4.

In the case of a user rate of 64 kbit/s, the octets are transmitted to line in bit sequence from bit 1 to bit 8. Network-provided octet alignment shall be used.

In the case of a user rate of 56 kbit/s, the data is transmitted to line in bit sequence from bit 1 to bit 7 followed by an 8th bit set to ONE – according to this Recommendation, rate adaption (in total this is the equivalent data stream to 64 kbit/s). Network-provided octet alignment shall be used.

In the case of user rates of 4.8, 9.6 or 19.2 kbit/s, the octets are packaged as single start-stop characters, using the following format:

- 1 start bit;
- 8 data bits (in order of transmission shown in Figure I.3);
- No parity; and
- 1 stop bit.

Figure I.3/V.110 – Asynchronous character format

bit 8: Set to ONE (and ignored on receipt)

NOTE – Equivalent data stream to that for 64 kbit/s is created with 56 kbit/s when rate adaption according to this Recommendation is used.

bit 7: Set to ZERO for IPE data

Set to ONE for IPE signal

For IPE data

bit 6: Set to ONE

(Set to ZERO: message reserved for private use and ignored if not implemented)

bit 5: Set to ZERO when carrying data bits d0-d3

Set to ONE when carrying data bits d4-d7

bits 1-4: Carrying data bits (d0-d3) or (d4-d7)

For IPE signal

bit 6: Set to ONE

(Set to ZERO: message reserved for private use and ignored if not implemented)

bit 5: Set to ZERO for command messages

Set to ONE for status messages

bits 1-4: The signal code

Figure I.4/V.110 – Octet structure of the IPE coding

Figure I.5 provides a complete set of octet codings for use in IPE.

Figure I.5/V.110 – IPE octet codings

I.6.2 Rate adaption version identification

Transfer of the rate adaption identifier is achieved by a message group based on three octets and transferred according to the procedures described in I.5.3.2 and I.5.9. The message consists of a sequence of RA VERSION command octets followed by a series of LOW-HIGH data octet pairs, the LOW data octet being transmitted in the pair before the HIGH data octet. Figure I.6 shows the message codings for rate adaption identification.

I.6.3 Control

Before each transfer of TA parameter information can begin, a sequence of XSTART command octets is transmitted by the originating TA towards the answering TA as described in I.5.3.2 and I.5.9. Figure I.7 shows the coding for the XSTART command octet.

I.6.4 Parameters

Transfer of the TA parameters is achieved in a series of five message groups each based on three octets and transferred according to the procedures described in I.5.3.2 and I.5.9. Each message group consists of a sequence of PARAM-X command octets (PARAM-0 to PARAM-4) followed by a series of LOW-HIGH data octet pairs, the LOW data octet being transmitted in the pair before the HIGH data octet. Figure I.8 shows the command octet codings and Figures I.9 to I.13 show the data octet codings for parameter transfer.

I.6.5 Status

To inform the peer TA that a parameter exchange has been successful, a sequence of READY status octets shall be transmitted towards the peer according to the procedures in I.5. Figure I.14 shows the coding for the READY status octet.

To inform the peer TA that it is in an idle condition prior to parameter exchange, a sequence of IDLE status octets are transmitted towards the peer according to the procedures in I.5. Figure I.15 shows the message coding for the IDLE status octet.

The FILL status octet is used as a fill between parameter transfers, according to the procedures in I.5. Figure I.16 shows the coding for the FILL status octet.

To inform the peer TA that the channel is currently inactive, a sequence of INACTIVE status octets are transmitted towards the peer according to the procedures in I.5. Figure I.17 shows the coding for the INACTIVE status octet.

NOTE 2 – Loop definitions 4 and 5 are defined in the I.600-series Recommendations.

NOTE 3 – Definitions are for the direction calling TA- to -called TA. In the reverse direction, they represent confirmation of the maintenance function.

Figure I.18/V.110 – Coding of MAINTENANCE message group

I.7 Timer values

I.7.1 Timer values for parameter exchange

Timer T1 shall be at least 8 s but less than timer T1 in 7.1.2.2.

Timer T2 shall be 3 s.

I.7.2 Timer values for maintenance

Timer T3 shall be 60 s.

I.8 State transition diagrams

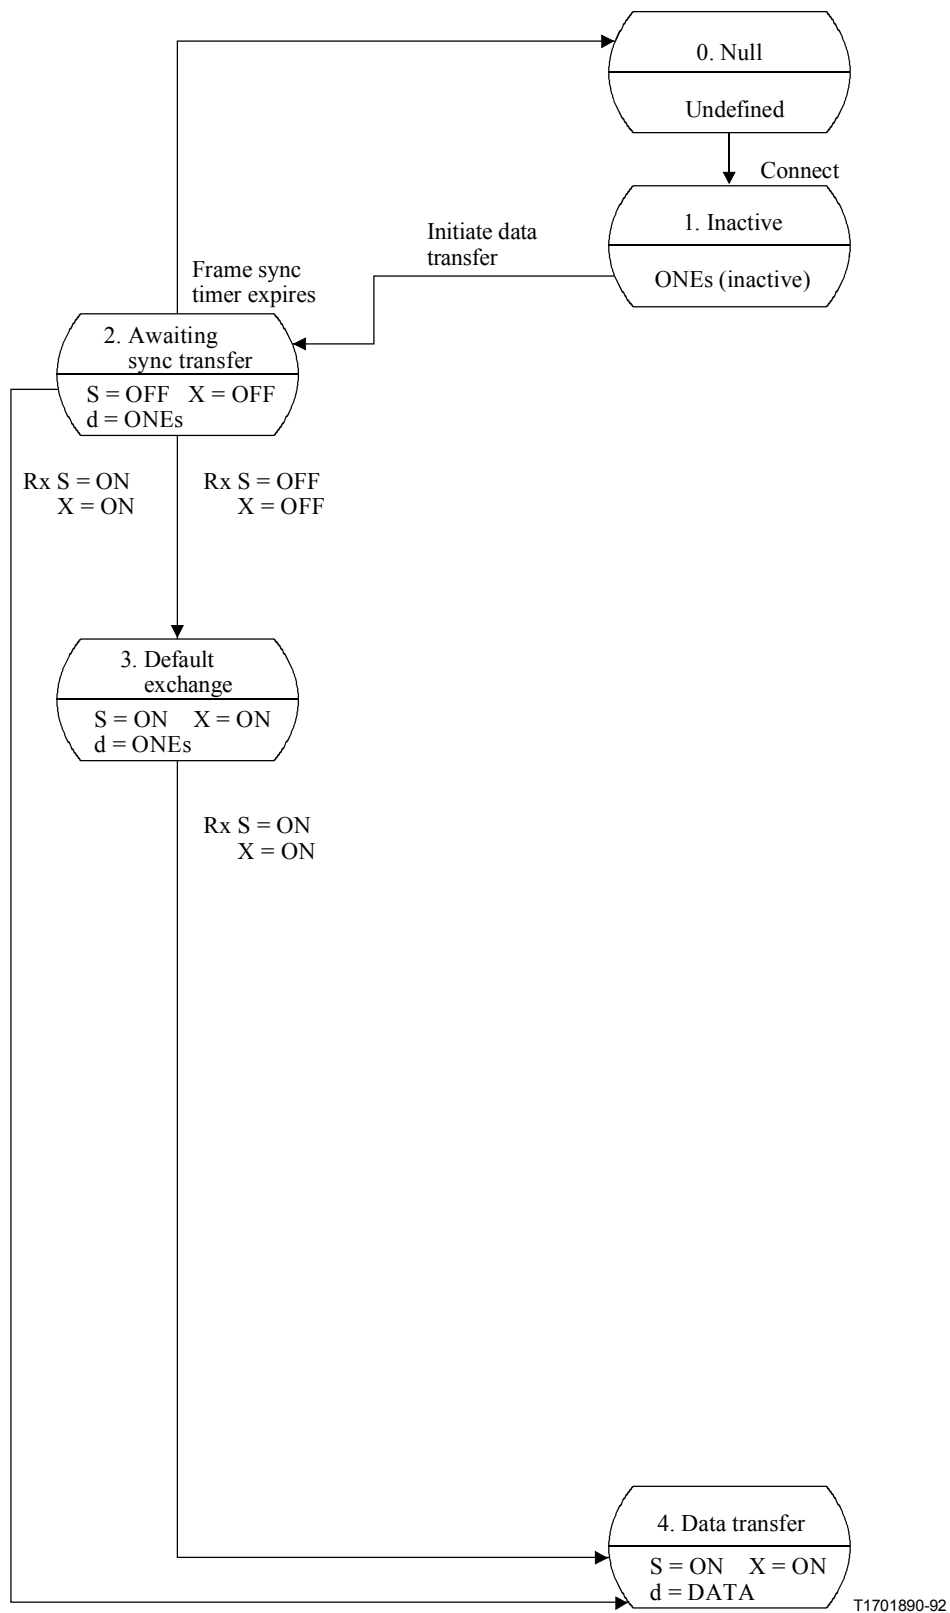

I.8.1 General

In this subclause, state transition diagrams are provided to show the states of a terminal adaptor in the following situations:

- terminal adaptor not supporting the exchange of parameter information (Figure I.19);
- terminal adaptor interworking with a terminal adaptor not supporting the exchange of parameter information (Figure I.20);
- terminal adaptor capable of supporting the exchange of parameter information (Figure I.21);
- terminal adaptor capable of supporting a maintenance test loop 4 (Figure I.22).

Following is a summary of the basic states involved:

State 0	Null
State 1	Inactive
State 2	Awaiting synchronization – Data transfer
State 3	Default exchange
State 4	Data transfer
State 5	IPE default exchange
State 6	Awaiting synchronization – Parameter exchange
State 7	Parameter exchange
State 8	Awaiting re-synchronization
State 9	No exchange
State 10	Awaiting re-entry to IPE
State 11	Maintenance loop 4 loopback

T1701890-92

NOTE – Release sequences not shown.

APPENDIX II

V.25 *bis* to Q.931 protocol mapping

II.1 General

The D-channel signalling capabilities of the ISDN customer-access are as defined in Recommendation Q.931. The mapping of the V.25 *bis* interface signalling procedures to the Q.931 protocol at the S/T reference point are described below.

The logical representation of this mapping function is shown in Figure II.1.

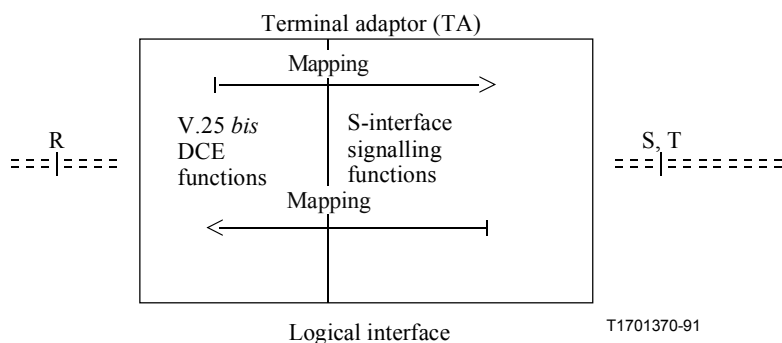

Figure II.1/V.110 – Terminal adapter V.25 *bis* mapping

The D-channel signalling capabilities provided to V.25 *bis* based terminals shall comprise the signalling messages as defined in Recommendation Q.931.

The following description and figures depict examples of V.25 *bis* mapping to the ISDN call control procedures. It is recognized that other possibilities and user options exist. But this subclause is intended to provide general guidelines for a satisfactory means of V.25 *bis* support. Only the normal call establishment and clearing procedures are shown. The following subclauses are titled with the terms of signalling messages at the S-interface.

Recall of the circuit list involved in the V.25 bis call set-up

- Ready for sending (106).
- Data set ready (107).
- Data terminal ready (108/2).
- Transmit data (103).
- Receive data (104).
- Calling indicator (125).

This appendix deals with call establishment and clearing. Any specific use of V.24 interchange circuits herein described only applies during these phases. The management of interchange circuits during the data transmission phase is not part of this appendix.

The state of other interchange circuits is not part of this appendix. However, to ensure maximum compatibility with existing equipment, the other interchange circuits provided should retain their normal function as defined in Recommendation V.24 during the automatic call procedure.

Particularly to ensure correct operation of the DTE, the condition of circuit 109 should follow the condition of circuit 106.

The DTE may choose to hold circuit 105 ON during the automatic calling procedure, but the TA is not required to recognize this condition.

II.2 Call origination

II.2.1 Call set-up

II.2.1.1 From TA

In the DTE ready state (see Recommendation V.25 *bis*), the present circuit 108/2 ON and 103 = '1'. The TA presents 106 = OFF, 107 = OFF, 125 = OFF and 104 = '1' (state 2 of the V.25 *bis* state diagram).

In response to detecting circuit 108/2 ON, the TA presents 106 ON which is equivalent to a Proceed to Select indication (X-Series Recommendations), and the DTE enters the DTE-DCE dialogue by presenting Call Request Command call request with identification (CRI) or call request with number (CRN). In response to 108/2 ON, the TA will have initiated the interface at the S/T reference point layer 1 activation as in Recommendation I.430.

The layer 2 at the interface at the S/T reference point shall be established on request of layer 3 when the set-up message is to be sent, according to Recommendation Q.931.

When the end of the valid command is received at the R-interface, the TA transmits a set-up message via the D-channel requesting the unrestricted 64-kbit/s bearer capability, for a transfer in circuit mode.

The user may also specify the layer 1 terminal adaption in the low layer compatibility information element of the call SETUP message. (See Annex L/Q.931 entitled *Low layer information coding principles*.)

The called party address information element shall be encoded *en bloc* with the complete address of the called party as received from the V.25 *bis* interface.

II.2.1.2 SETUP acknowledge/call proceeding (from exchange)

The network reaction on the SETUP message received from the TA can be either:

- Sending of a CALL PROCEEDING
When the call proceeding message is received on the D-channel of the interface at the S/T reference point, the B-channel will be allocated and the TA connects to the B-channel.
- Sending a SETUP Acknowledge
When the SETUP Acknowledge message to the TA is received on the D-channel at the interface at the S/T reference point, the B-channel will be allocated to the TA.

II.2.1.3 CONNECT (from exchange)

When a CONNECT is received on the D-channel at the interface at the S/T reference point, the TA transmits any DCE response to the calling DTE and enters state 5 Answer Tone Detected by turning 106 OFF.

The TA proceeds to the Connect to Line state as described in 7.1.2 completing the V.25 *bis* control phase with circuit 107 ON.

II.2.2 Call received from remote DTE/TA

II.2.2.1 Call SETUP (from exchange)

The TA should accept a SETUP message regardless of the V.25 *bis* interface state 1 or state 2. When a SETUP message is received on the D-channel at the S interface, the TA shall follow the procedures for determining compatibility checking (data signalling rate) found in Recommendation Q.931. If the TA determines that it can respond to the incoming call, it follows the procedures of Recommendation Q.931.

The TA indicates an incoming call via the V.25 *bis* interface by setting 125 = ON, 104 = '1' and 107 = OFF; thereby entering state 8 Incoming Call.

If the DTE does not present 108/2 = ON within a timer time T', the TA rejects the call with a CALL REJECT indicating no answer from DTE.

II.2.2.2 CONNECT (from TA)

When state 9 Incoming Call Recognized is presented by the DTE turning circuit 108/2 ON (note that this may be immediate if the DTE presents 108/2 permanent ON) to accept the incoming call, the TA transmits a CONNECT message via the D-channel of the interface at the S/T reference point.

II.2.2.3 CONNECT Acknowledge (from exchange)

When a CONNECT Acknowledge message is received on the D-channel at the interface at the S/T reference point, the TA, selected by this message, signals Line Seized (state 13) by presenting circuit 125 = OFF to the DTE after presenting positive responses if any.

The TA proceeds to the Connect to Line state as described in 7.1.2 completing the V.25 *bis* call control phase with circuit 107 = ON.

II.3 Call clearing (Figures II.2 and II.3)

II.3.1 DISCONNECT (from TA)

A clearing by the DTE (state 7) 103 = '1' 108/2 = OFF is transmitted by the TA via the B-channel to the remote DTE.

The TA at the clearing DTE on recognizing state 7 at the V.25 *bis* interface, disconnects the circuits 103, 104 and 108/2 from the B-channel. The TA causes the status and data bits on the B-channel to correspond to circuit 108/2 OFF and 103 = '1' and awaits for Clearing Acknowledge from remote DTE (108/2 = OFF, 103 = '1') for a timer time of 10 s. The TA then transmits DCE Clear Confirmation by turning OFF 107 to the clearing DTE (no corresponding state of the V.25 *bis* interface). It also transmits a DISCONNECT message via the D-channel at the interface at the S/T reference point.

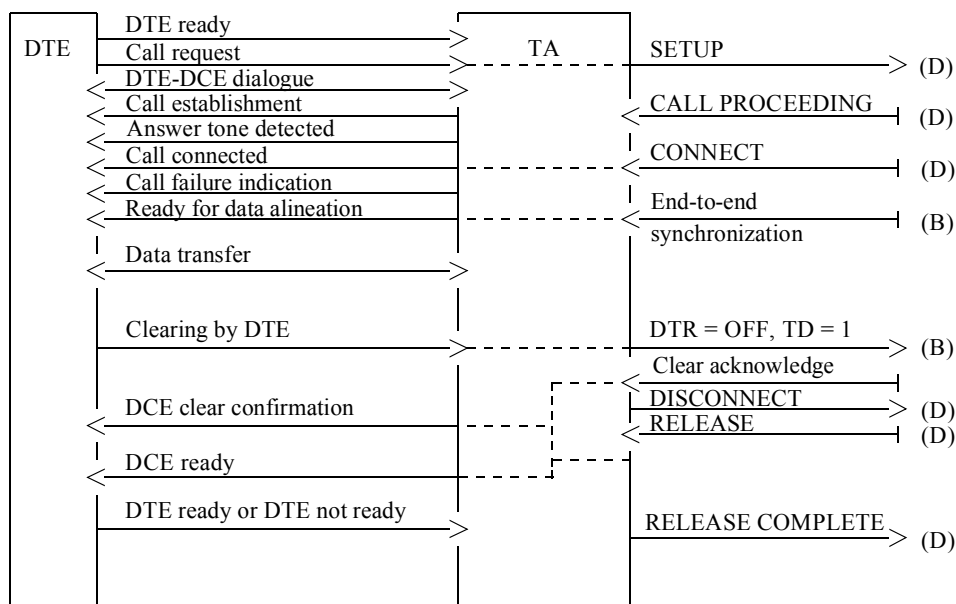

After reception of the RELEASE message on the D-channel, the TA sends RELEASE COMPLETE to the exchange, and the DTE enters DTE Ready or DTE Not Ready states.

II.3.2 DISCONNECT (from exchange)

In the case of the clearing by the network, the local exchange transmits the DISCONNECT message via the D-channel to the TA to be cleared. After reception of the DISCONNECT message in the TA, the TA transmits a RELEASE message on the D-channel to the exchange.

If the V.25 *bis* interface is in the call establishment phase and has not yet reached state 5, 6 or 12, and if the DISCONNECT contains the reason for clearing, the TA moves to DTE-DCE dialogue state 3 and transmits the corresponding Call Failure Indication to the DTE prior to Call Clearing.

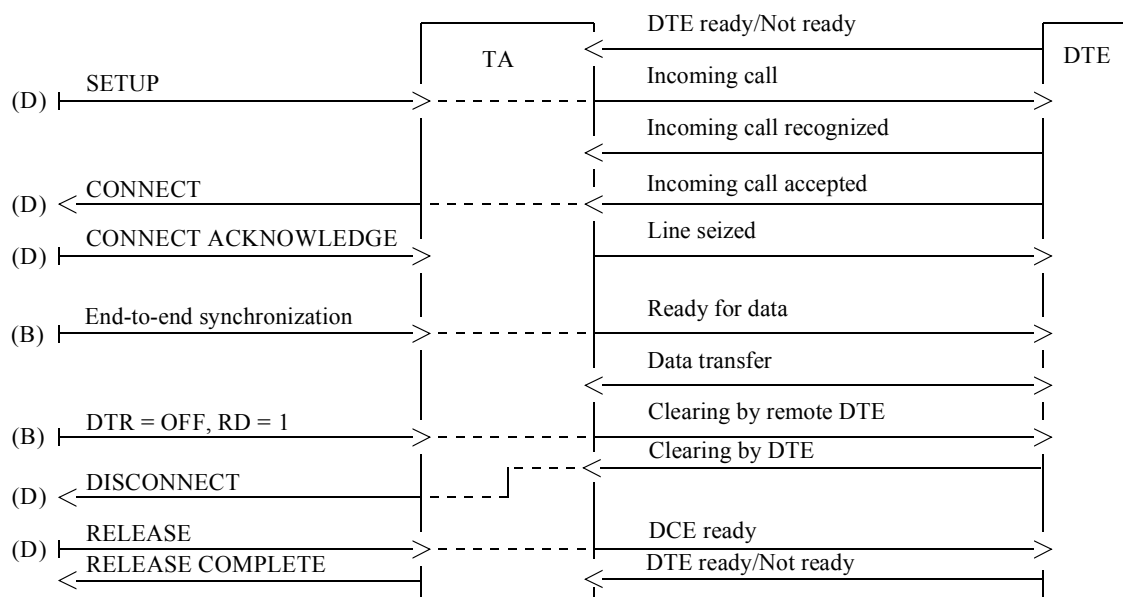

Otherwise the TA transmits the DCE clear indication (107 = OFF, 103 = '1'), via the V.25 *bis* interface to the DTE, which sends back to the TA the DTE Clear Confirmation which is identical to Clearing by DTE 108/2 = OFF, 104 = '1' as described in 4.3.3/V.24, (no V.25 *bis* interface states). If the DTE does not present 108/2 = OFF within a timer "T", the TA sends DISCONNECT to the D-channel at the expiration of the timer.

T1701390-91

RD Received Data

Figure II.3/V.110 – Recommendation V.25 *bis* – Example of DCT call establishment and call clearing

II.3.3 DISCONNECT (In-band between TAs)

When the DTE initiates the Clearing by DTE, this status is transmitted in slot within the B-channel and received as DCE clear indication equivalent to a PSTN disconnect in the DTE 107 = OFF.

The TA recognizes the clear request received in-band via the B-channel at the interface at the S/T reference point, separates the 103 108/2 leads from the B-channel and transmits to the DTE the DCE Clear Indication, 104 = OFF, 107 = OFF.

After the DTE to be cleared has received DTE Clear Confirmation, (108/2 = OFF, 104 = '1') from the clearing DTE, it transmits a DISCONNECT message via the D-channel, and clears the B-channel.

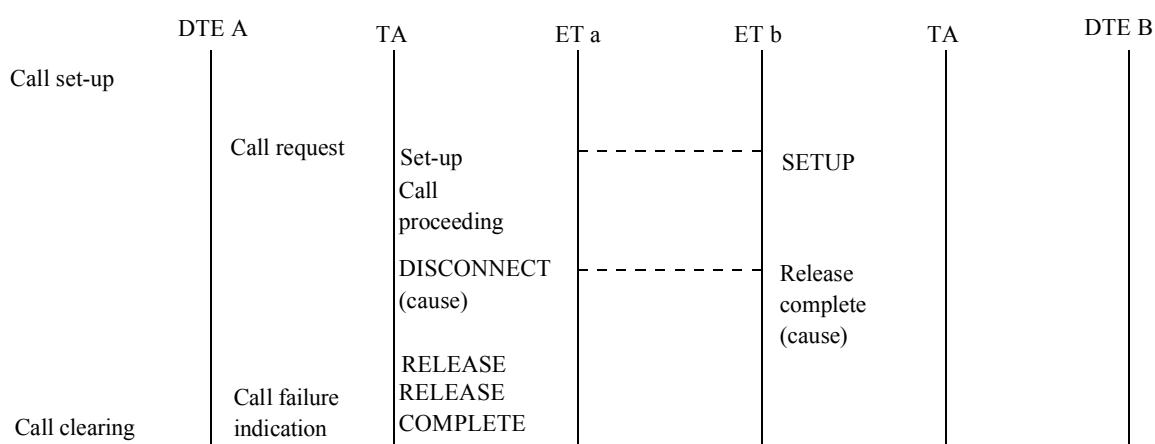

After reception of a release message on the D-channel, the TA releases the call reference, sends a RELEASE COMPLETE message to the exchange, and the V.25 *bis* interface enters the state DTE Not Ready or DTE Ready depending on the state of 108/2.

II.3.4 RELEASE COMPLETE

When the RELEASE COMPLETE is received via the D-channel at the interface at the S/T reference point of the TA of the cleared DTE, the V.25 *bis* interface enters DTE Ready or DTE Not Ready depending on the state of circuit 108/2.

II.3.5 Negative response to an incoming call

RELEASE COMPLETE message, including the appropriate case code, is sent by a TA supporting a terminal which is compatible with information contained in the SETUP message, to indicate that the call cannot be accepted at this time for the following reason: busy condition of the called terminal (see Figure II.4).

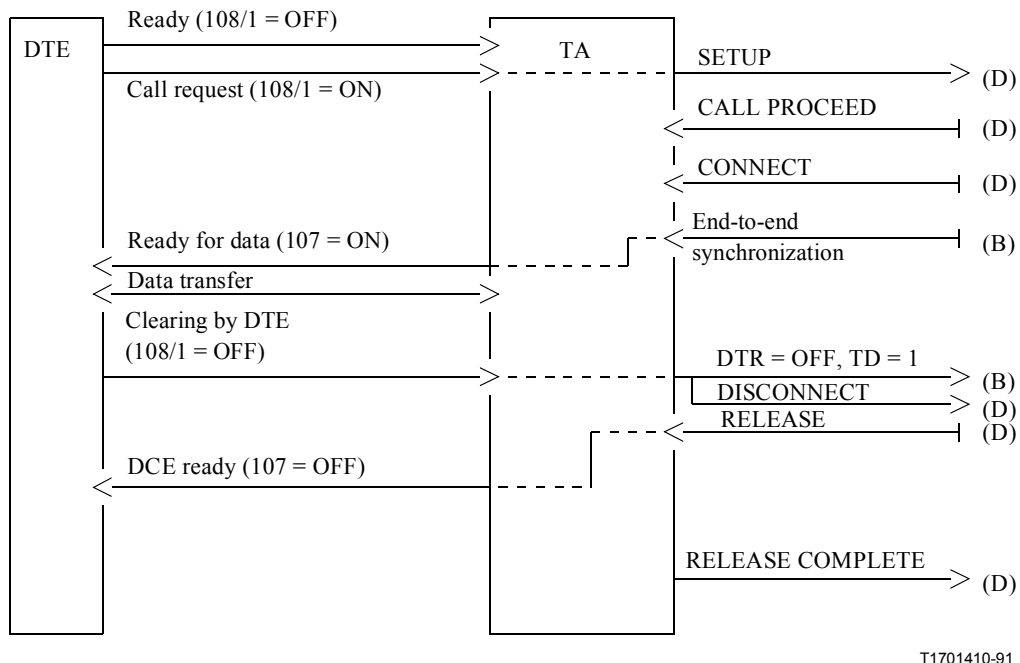

T1701400-91

Figure II.6/V.110 – Recommendation V.25 *bis* – Direct DCE call establishment and call clearing

II.5 Mapping of Q.931 causes to V.25 *bis* call failure indications and responses

In several cases, it will be necessary to map causes from Recommendations Q.931 to V.25 *bis* indications. The TA shall use Table II.1 to map the causes from Q.931 messages to V.25 *bis* Call Failure Indication or Call Progress Signals. The cause codes are provided by the ISDN to the TA.

Handling of the Call Failure Indication (CFI) by the DTE may be a national matter. CFI (AB) is to be taken by the DTE as no use for the DTE to call again, some changes need to be done within the DTE before the call can be successful; CFI (ET) is to be taken by the DTE as a transient condition, the DTE may retry the call without changes; CFI (NT) indicates a serious failure of the call and the DTE should wait before retrying the call. CFI (INV) is reserved for local invalid commands and is not a mapping of an ISDN cause code.

Not all Q.931 causes will be reported to the R interface. The general principles kept in Table II.1 are to distinguish between normal events (in a call) causes 0 to 31, resource unavailable causes 32 to 47, service not available causes 48 to 63, service not implemented causes 64 to 79, invalid message causes 80 to 95, protocol error causes 96 to 111, interworking causes 112 to 127.

Table II.1/V.110

Item	Q.931 cause	ISDN code	V.25 <i>bis</i> call response	V.25 <i>bis</i> code
1	Unassigned or unallocated number	1	Not obtainable	AB
2	No route to specified transit network	2	Not obtainable	NT
3	No route to destination	3	Not obtainable	AB
4	Channel unacceptable	6	Not obtainable	ET
5	Call awarded and being delivered in an established channel	7		AB
6	Normal call clearing	16	Not applicable	None
7	User busy	17	Number busy	ET
8	No user responding	18	No connection	NT
9	No answer from user (user alerted)	19	No connection	NT
10	Call rejected	21	No connection	NT
11	Number changed	22	Changed number	AB
12	Non-selected user clearing	26	No connection	AB
13	Destination out of order	27	No connection	NT
14	Invalid number format (address incomplete)	28	Selection signals error	AB
15	Facility rejected	29		AB
16	Respond to status ENQUIRY	30		AB
17	Normal, unspecified	31		AB
18	No circuit/channel available	34	No connection	ET
19	Network out of order	38	No connection	NT
20	Temporary failure	41	Out of order	NT
21	Switching equipment congestion	42	Network congestion	NT
22	Access information discarded	43	No connection	NT

Table II.1/V.110 (continued)

Item	Q.931 cause	ISDN code	V.25 bis call response	V.25 bis code
23	Requested circuit/channel not available	44	No connection	ET
24	Resource unavailable, unspecified	47	Network congestion	NT
25	Quality of service unavailable	49		AB
26	Requested facility not subscribed	50		AB
27	Bearer capability not authorized	57	Incompatible user class	AB
28	Bearer capability not presently available	58	Network congestion	ET
29	Service or option not available, unspecified	63	No connection	AB
30	Bearer capability not implemented	65	Invalid facility request	AB
31	Channel type not implemented	66	Invalid facility request	AB
32	Requested facility not implemented	69	Invalid facility request	AB
33	Only restricted digital information bearer capability is available	70	Invalid facility request	AB
34	Service or option not implemented, unspecified	79	Invalid facility request	AB
35	Invalid call reference value	81		NT
36	Identified channel does not exist	82	No report	
37	A suspended call exists, but this call identity does not	83	No report	
38	Call identity in use	84	No report	
39	No call suspended	85	No report	
40	Call having the requested call identity has been cleared	86	No report	
41	Incompatible destination	88		AB
42	Invalid transit network selection	91	No report	
43	Invalid message, unspecified	95	No report	
44	Mandatory information element is missing	96	No report	
45	Message type non-existent or not implemented	97	Protocol error, no report	
46	Message not compatible with call state or message type non-existent or not implemented	98	Protocol error, no report	
47	Information element/parameter non-existent or not implemented	99	Protocol error, no report	
48	Invalid information element contents	100	Protocol error, no report	

Table II.1/V.110 (concluded)

Item	Q.931 cause	ISDN code	V.25 bis call response	V.25 bis code
49	Message not compatible with call state	101	Protocol error, no report	
50	Recuperation on timer expiry	102	No report	
51	Protocol error, unspecified	111	Protocol error, no report	
52	Interworking, unspecified	127	Not applicable	
NOTE – New call failure indication to report ISDN related situations at the V.25 bis interface is for further study.				

II.6 Additional information for handling of exception situations

When the call is cleared prematurely or a call failure occurs, the rules of Recommendations Q.931 and of V.25 bis apply. The following procedures are derived for the mutual mapping between the R and the S reference points.

II.6.1 Call collision

Incoming call from the exchange has priority on outgoing call to the exchange (for V.25 bis DTE which is normally attached to PSTN).

II.6.1.1 Call collision at the V.25 bis interface

The TA shall accept an incoming SETUP message. When at the V.25 bis interface a call collision is detected (TA presents incoming call indication, V.25 bis DTE presents call request), the TA will delay the outgoing call to monitor for incoming calls and will accept the incoming call and not process the outgoing call.

II.6.1.2 Call collision at the interface at the S/T reference point

The procedures defined in Recommendation Q.931 will apply.

II.6.2 No channel available

If no channel including no B-channel at the interface at the S/T reference point is available for connection establishment, an outgoing SETUP message is answered from the exchange by a RELEASE COMPLETE message with the cause 34 = no channel available. This is mapped at the V.25 bis interface in the call failure indication ET (Engaged Tone).

II.6.3 Premature call clearing

II.6.3.1 No answer to outgoing SETUP

If an outgoing SETUP is not answered by the exchange, the DTE will after a time out which is fixed by the national Administrations' T2 timer, initiate the clearing by DTE by dropping 108/2 = OFF. The TA on its S reference point, will send a RELEASE COMPLETE message (cause code 31: normal, unspecified). The V.25 bis interface will go back to DTE Ready or DTE Not Ready.

On the other hand, if a TA is provided with the optional timer T303 (see Recommendation Q.931) it may start the clearing procedure at the interface at the S/T reference point interface as above by transmitting RELEASE COMPLETE (cause code 102: recovery on timer expiry). At the V.25 bis interface, the TA sends the call failure indication No Tone.
